

An Armchair Guide:

To Quantum Mechanics

The
Armchair
Guide

Jonathan Allday

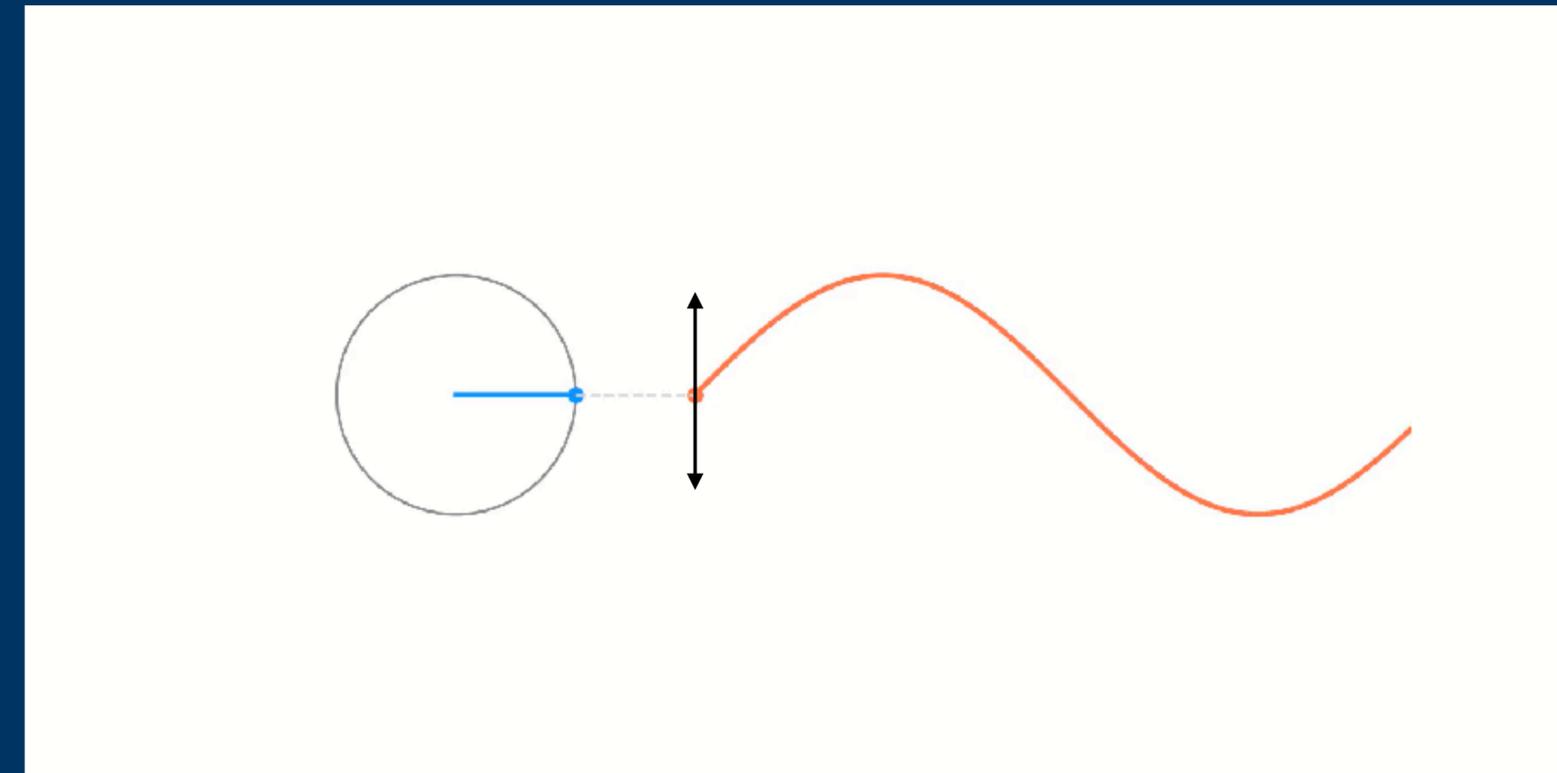

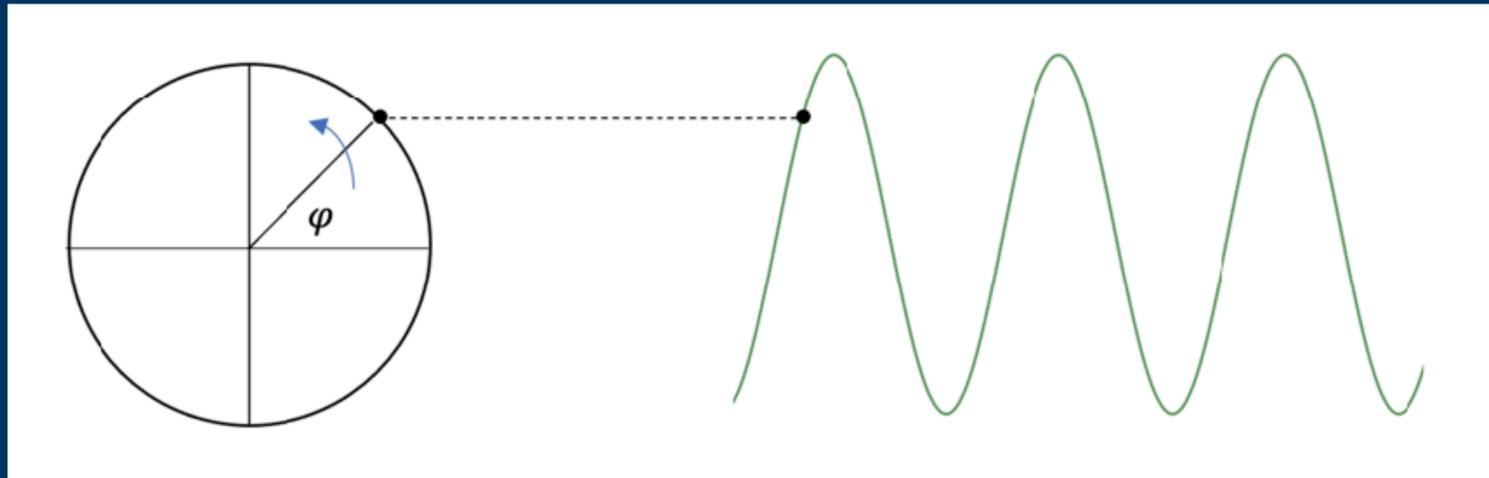

Session 4:

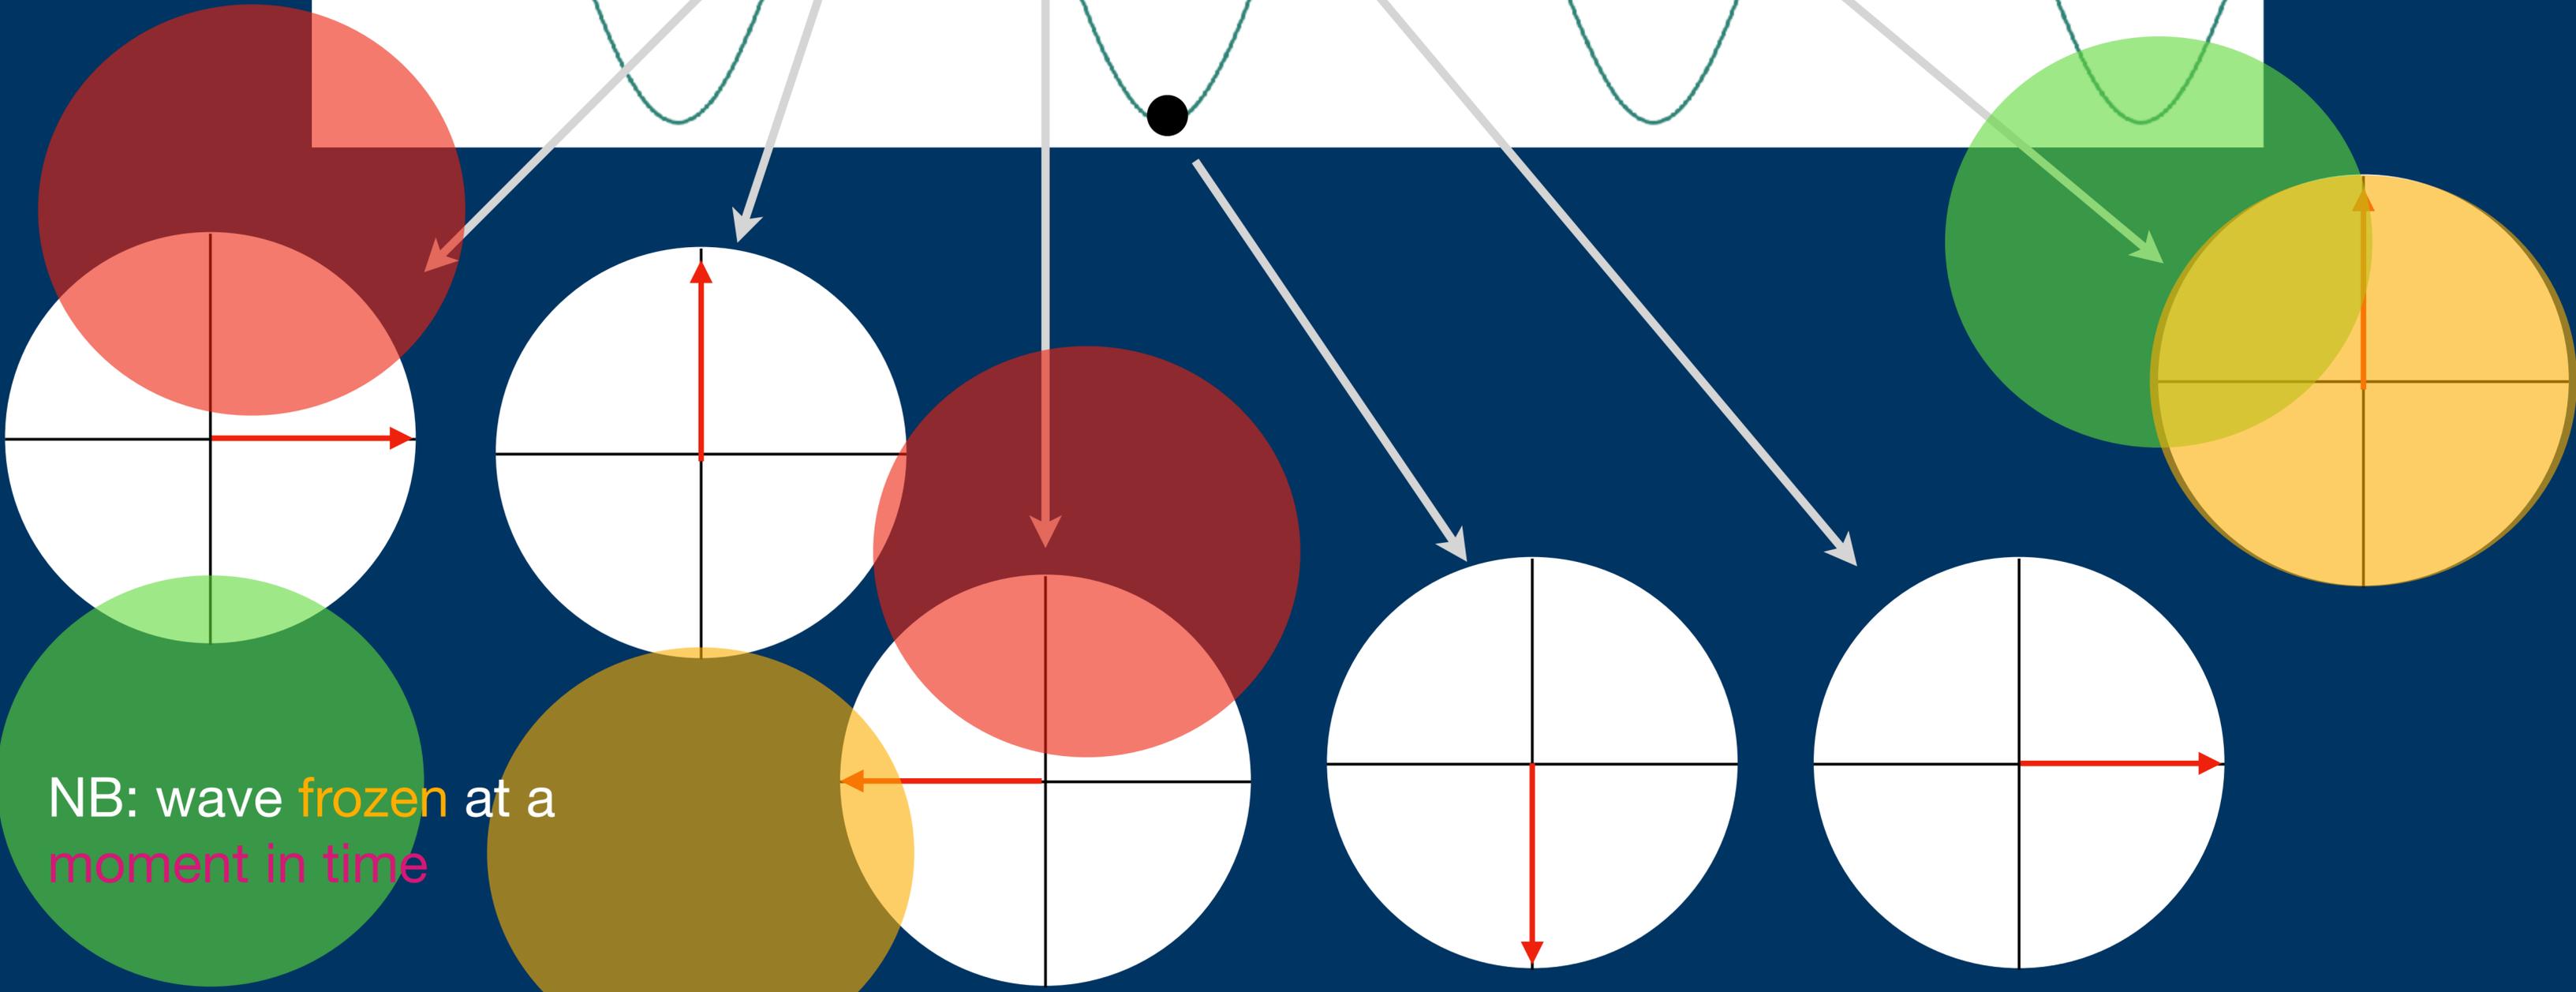

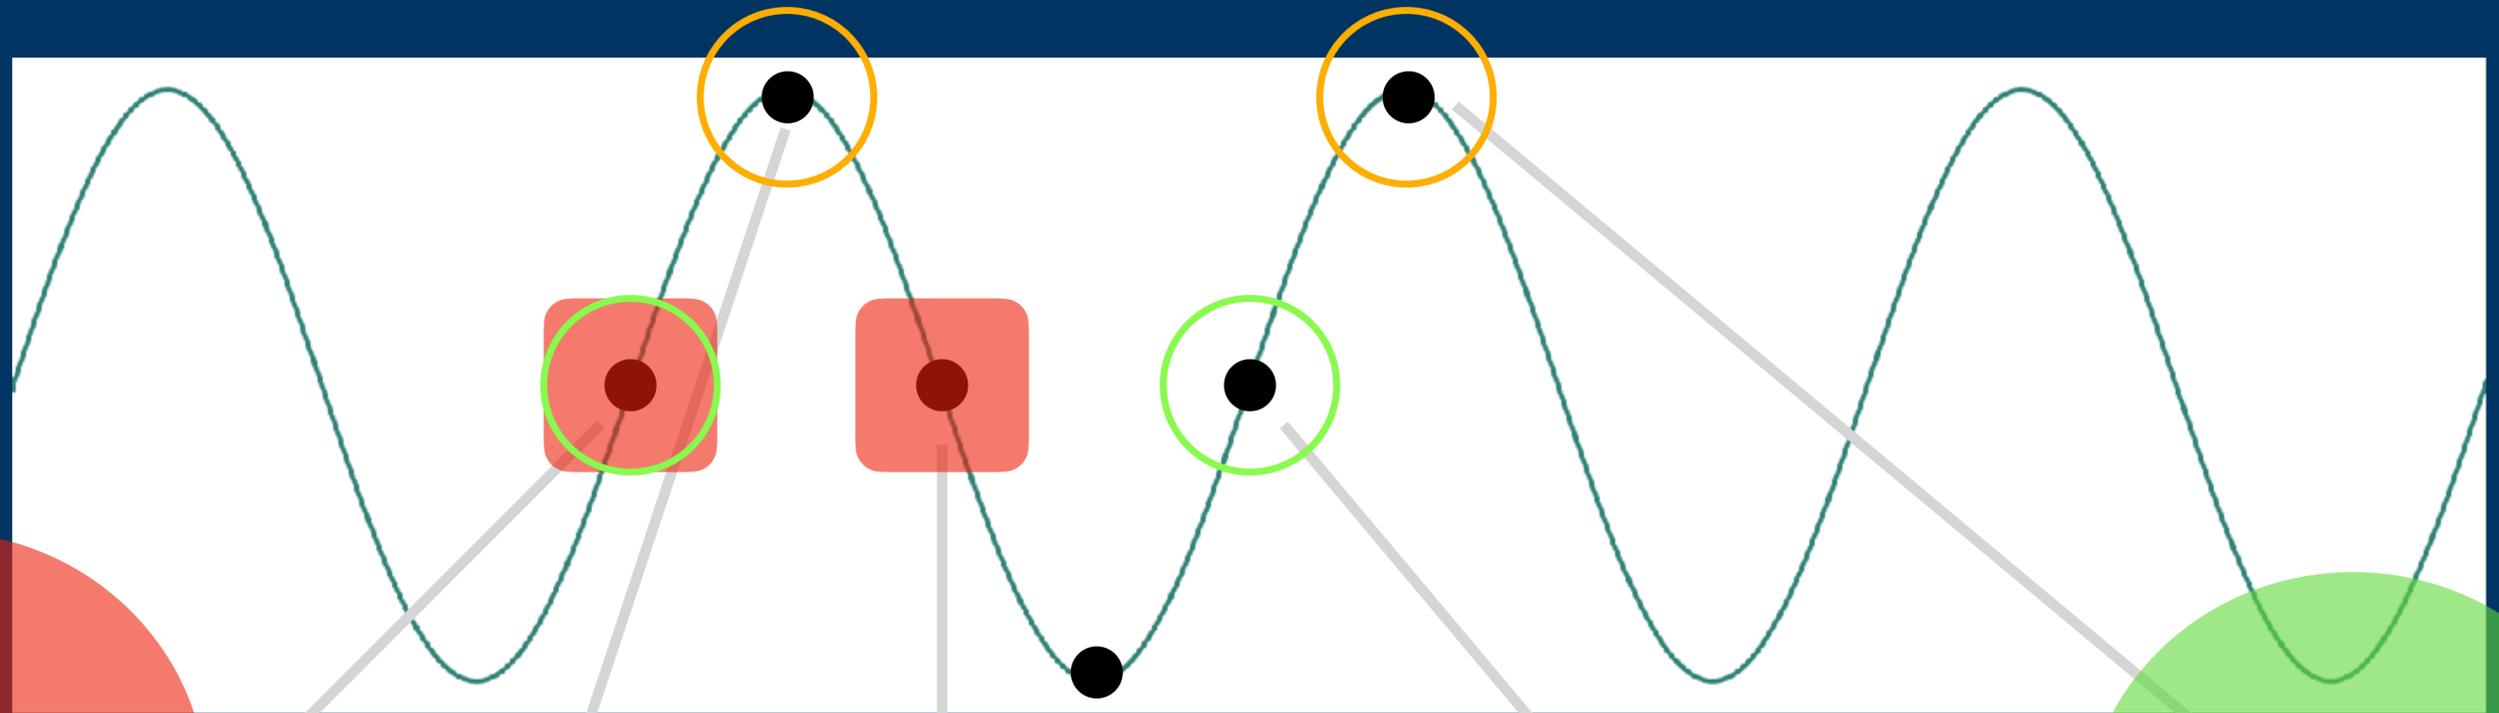

The Measurement Problem

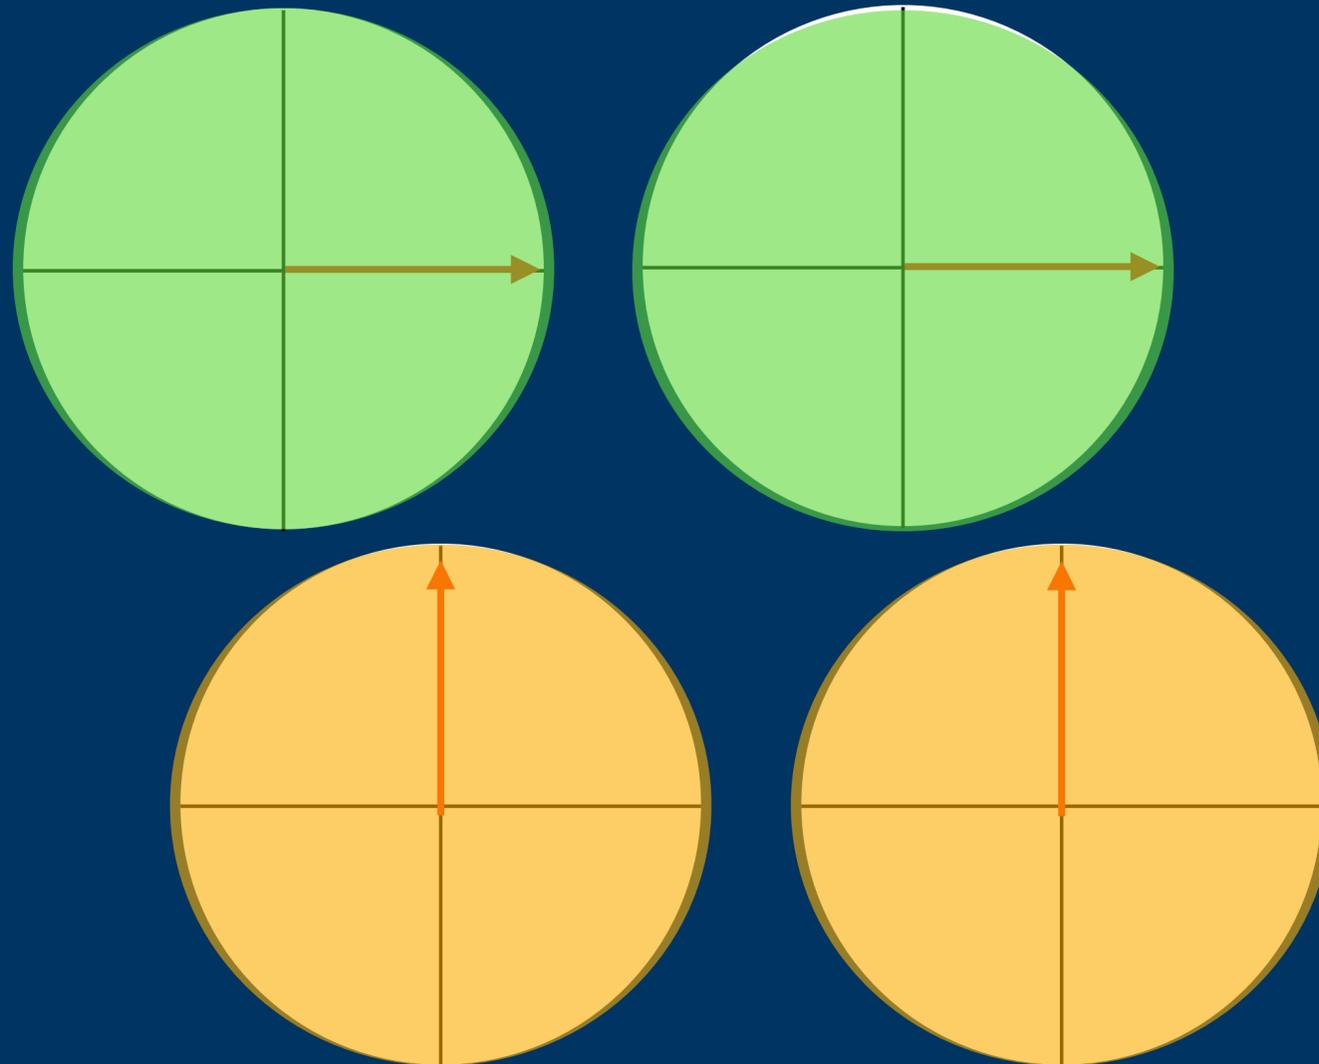

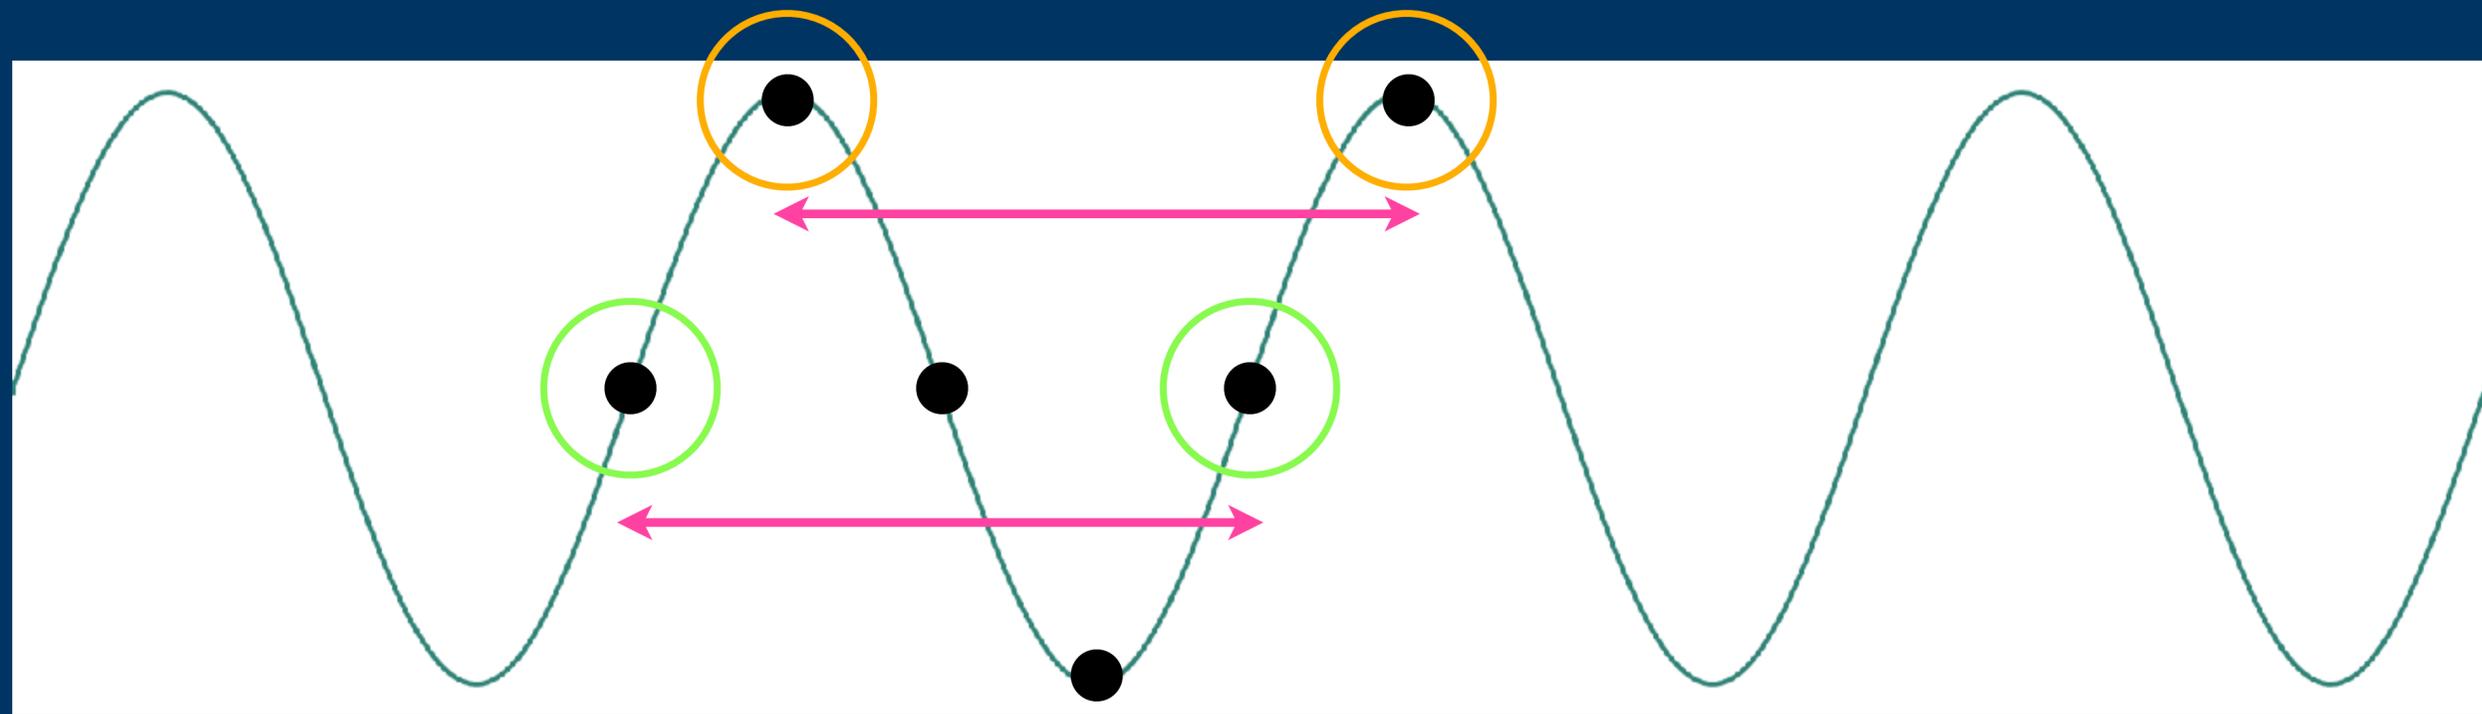

Wave **phase** - what part of the cycle

Specified as an **angle**...

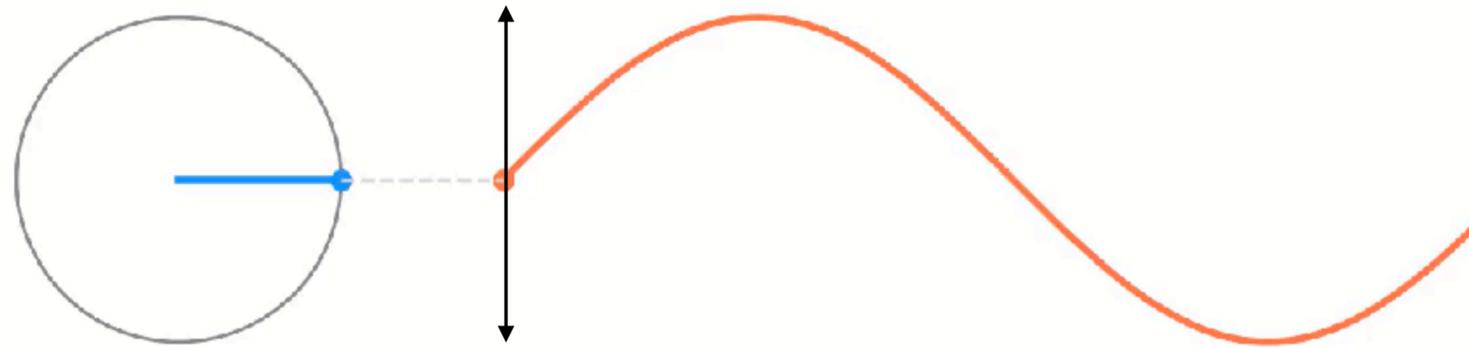

NB: wave frozen at a moment in time

Wavelength:

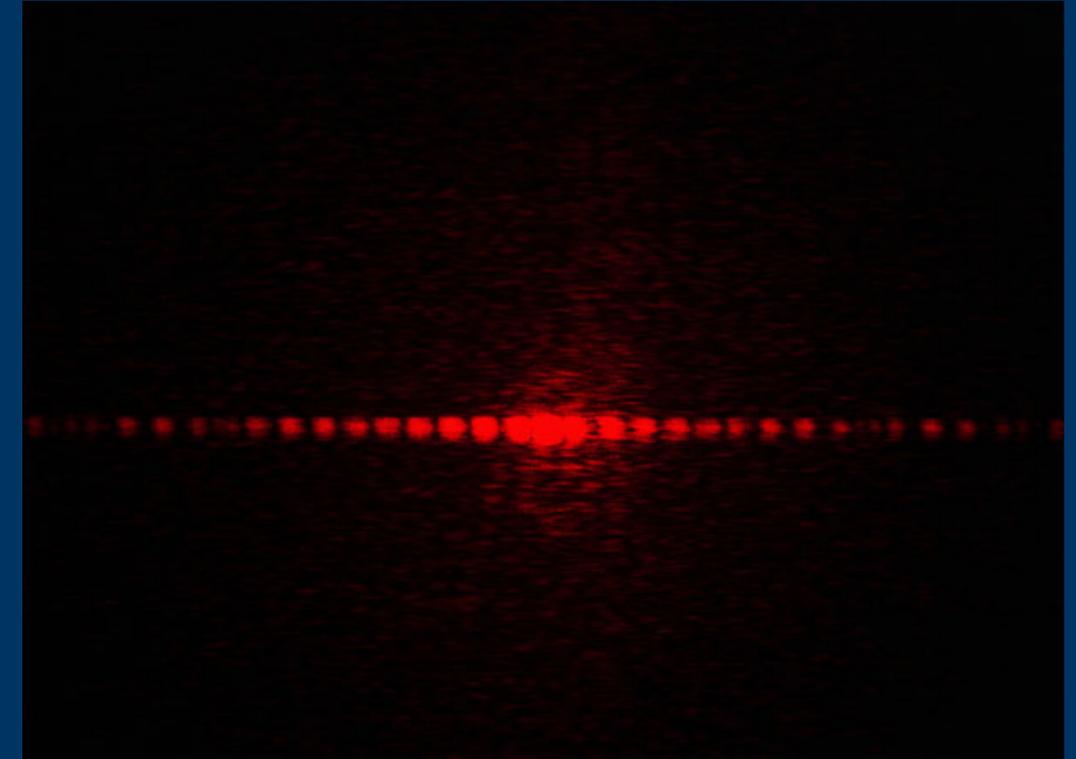

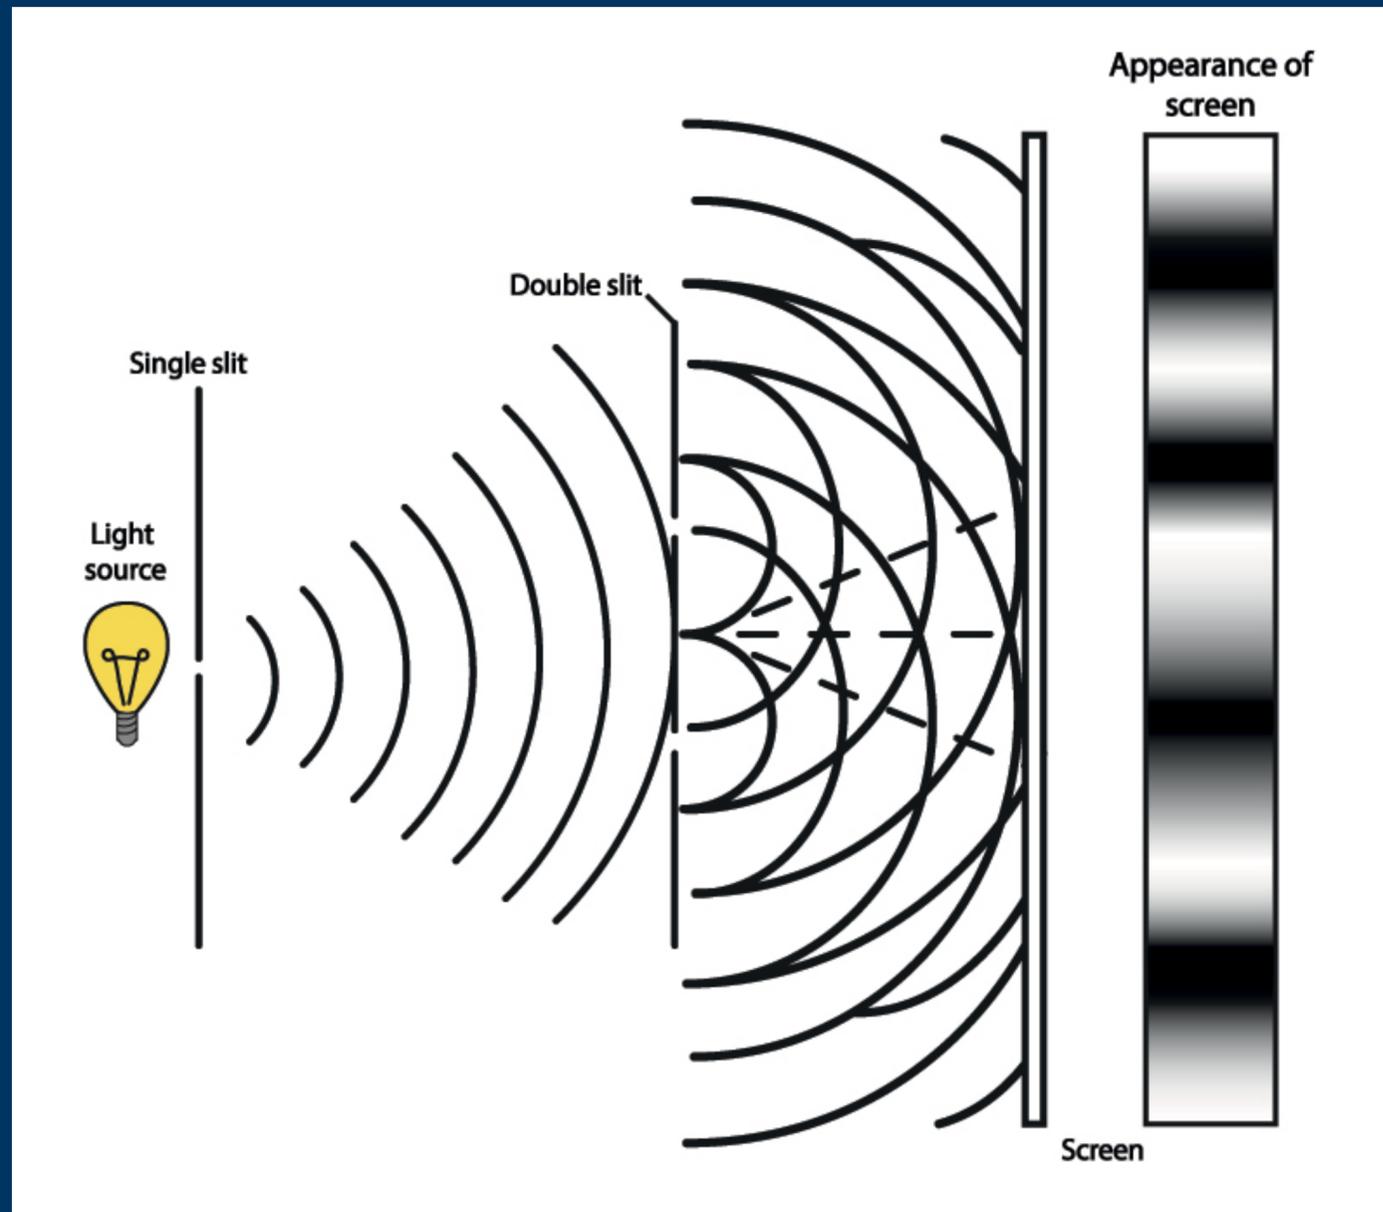

Shortest distance between
two points of the **same phase**

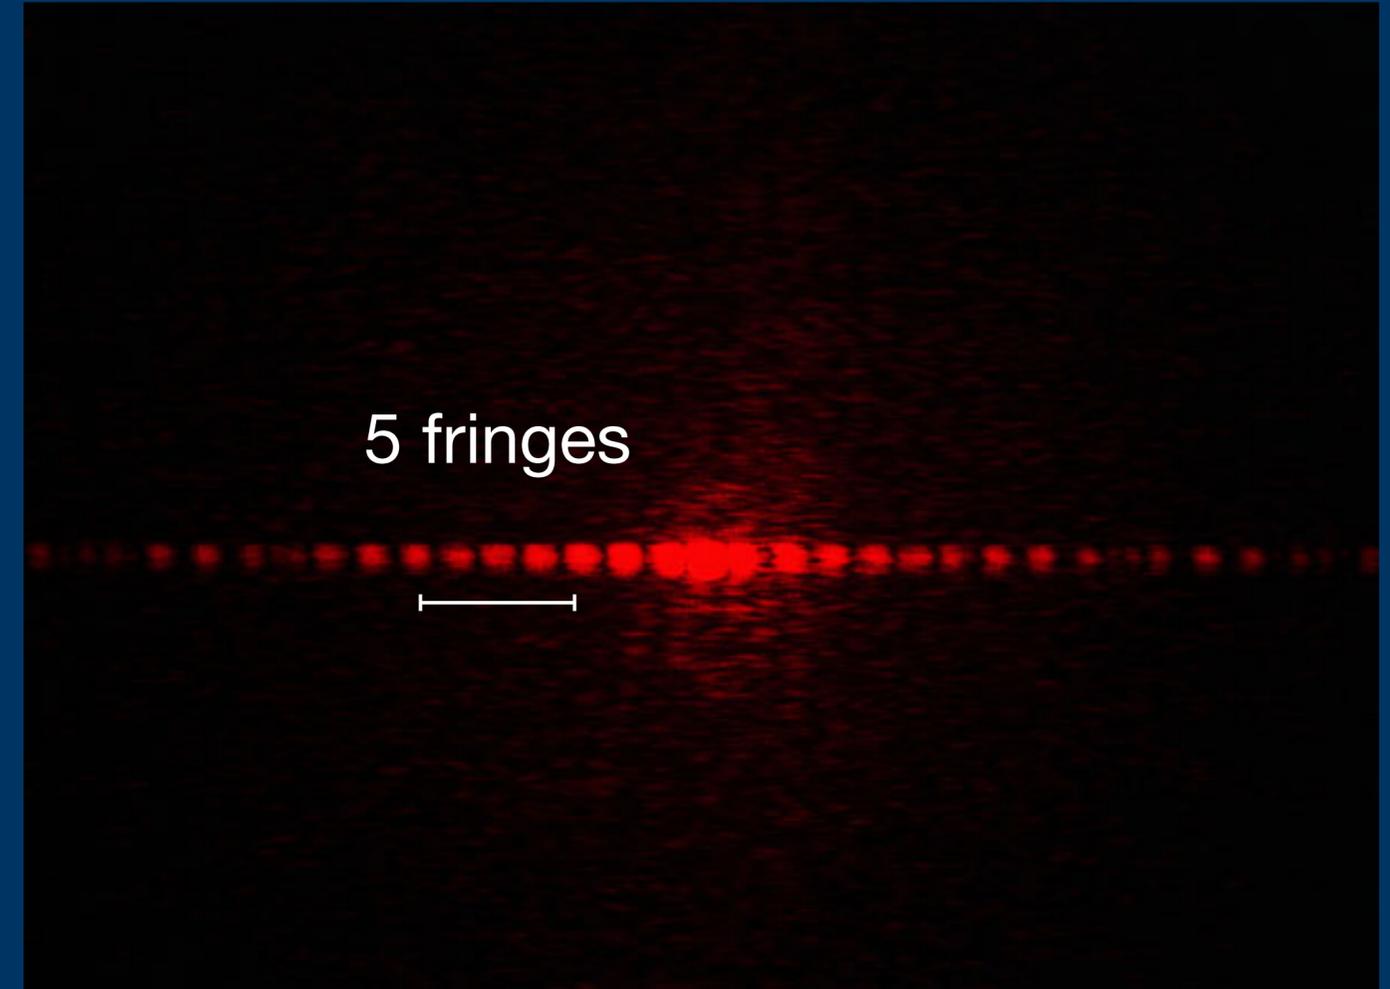

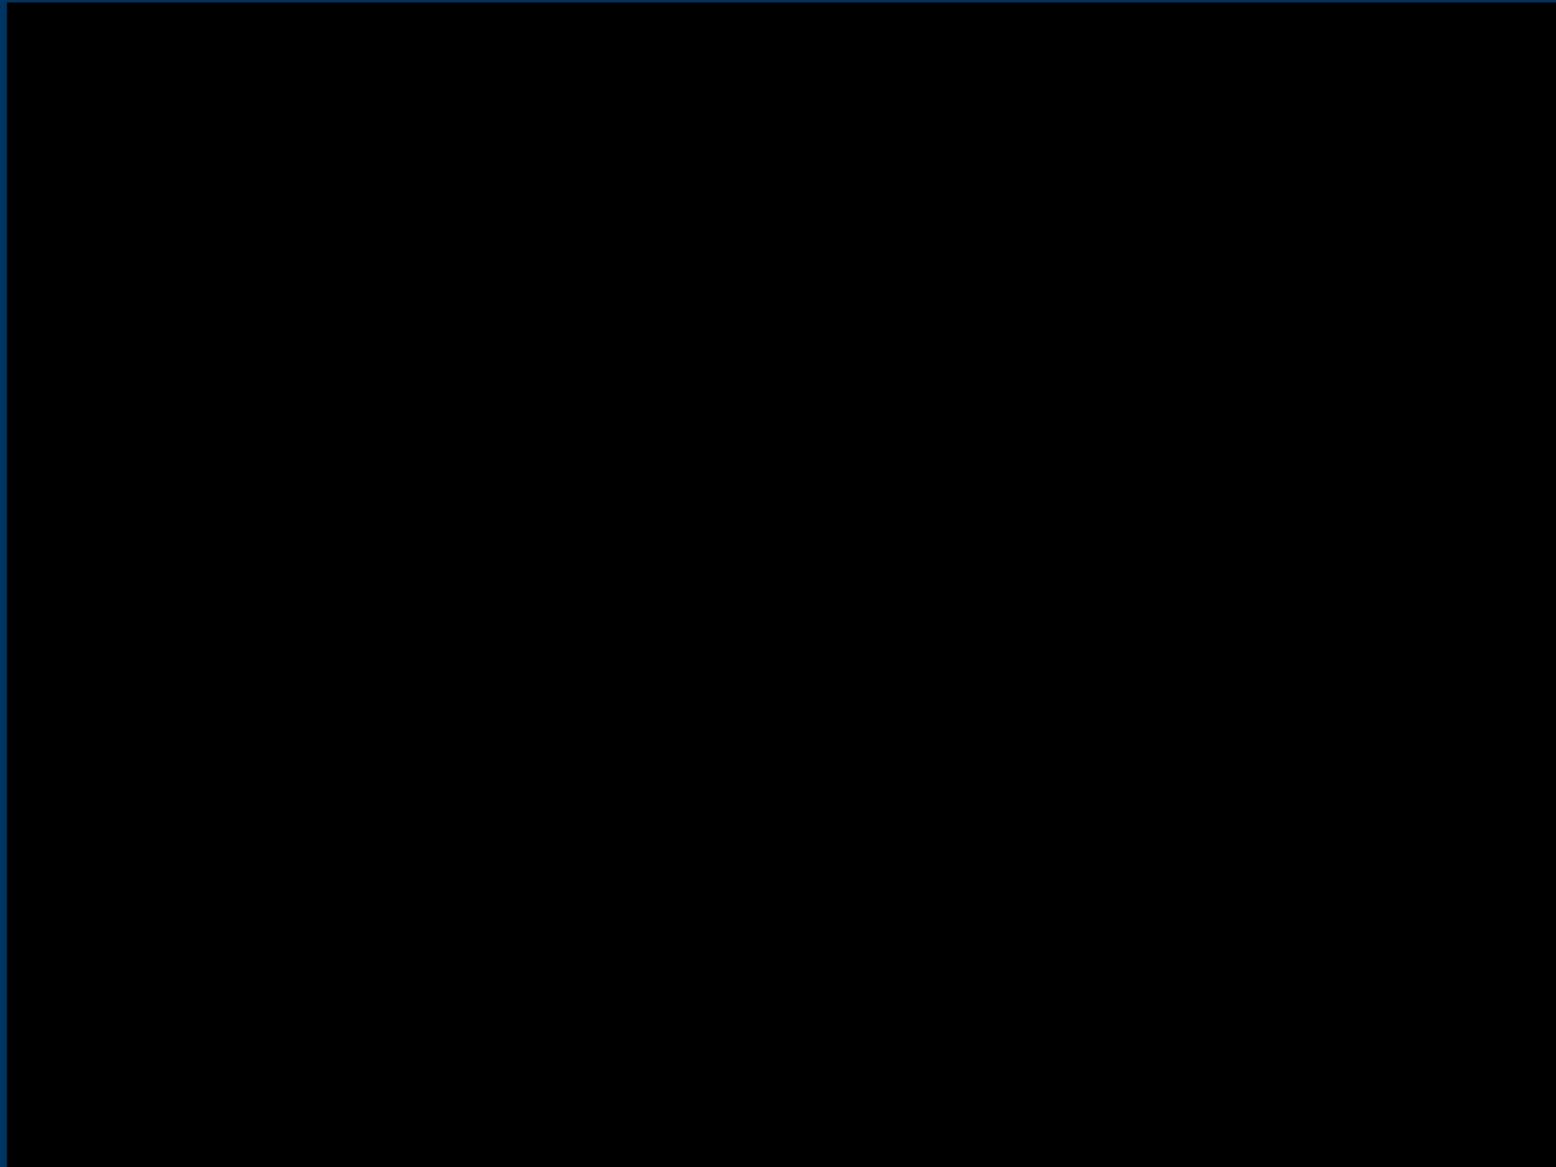

Frequency: **shortest time** taken to reach the **same phase again**

NB: **single place** on the wave **over time**

Double slit experiment with light

Double slit experiment with light

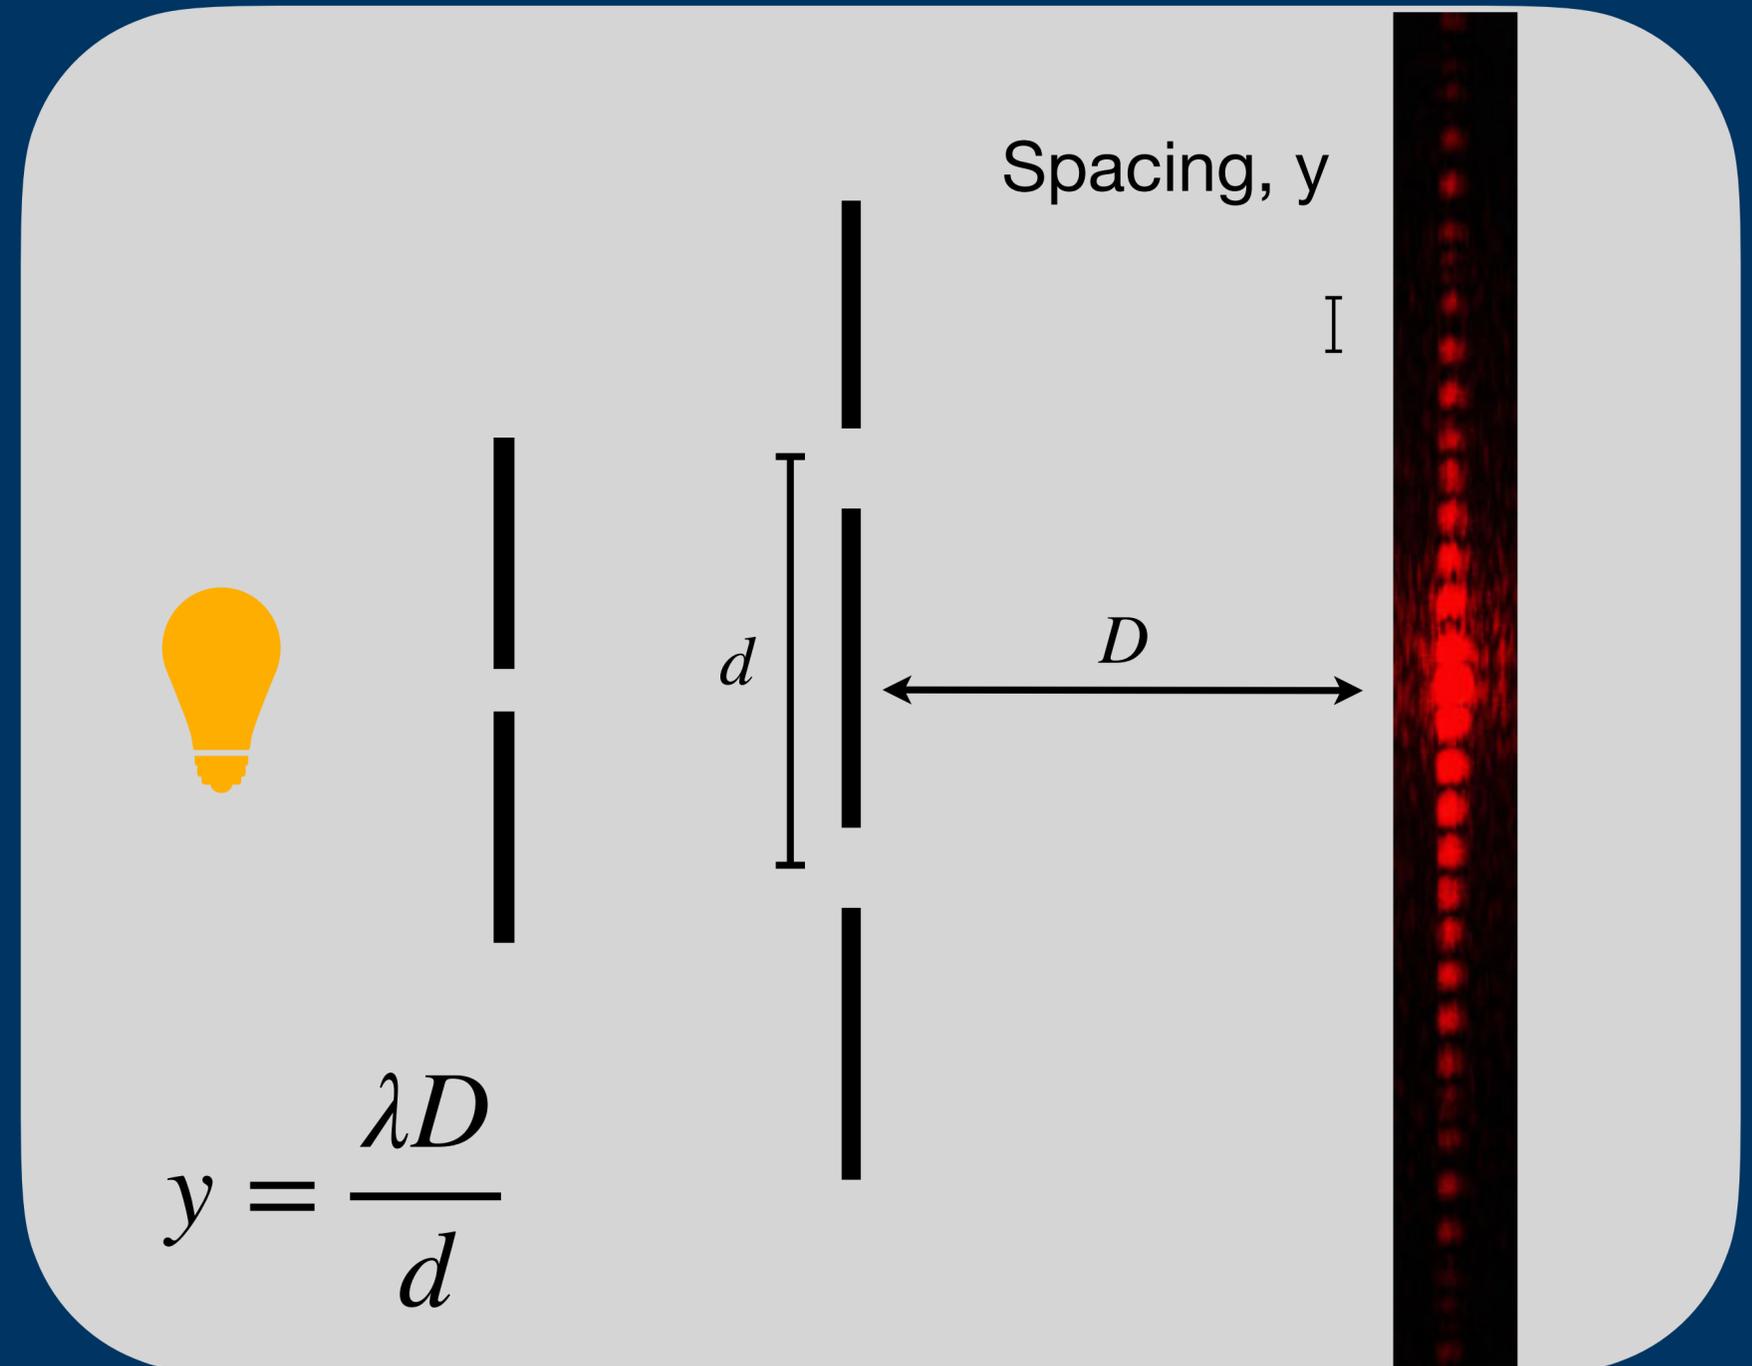

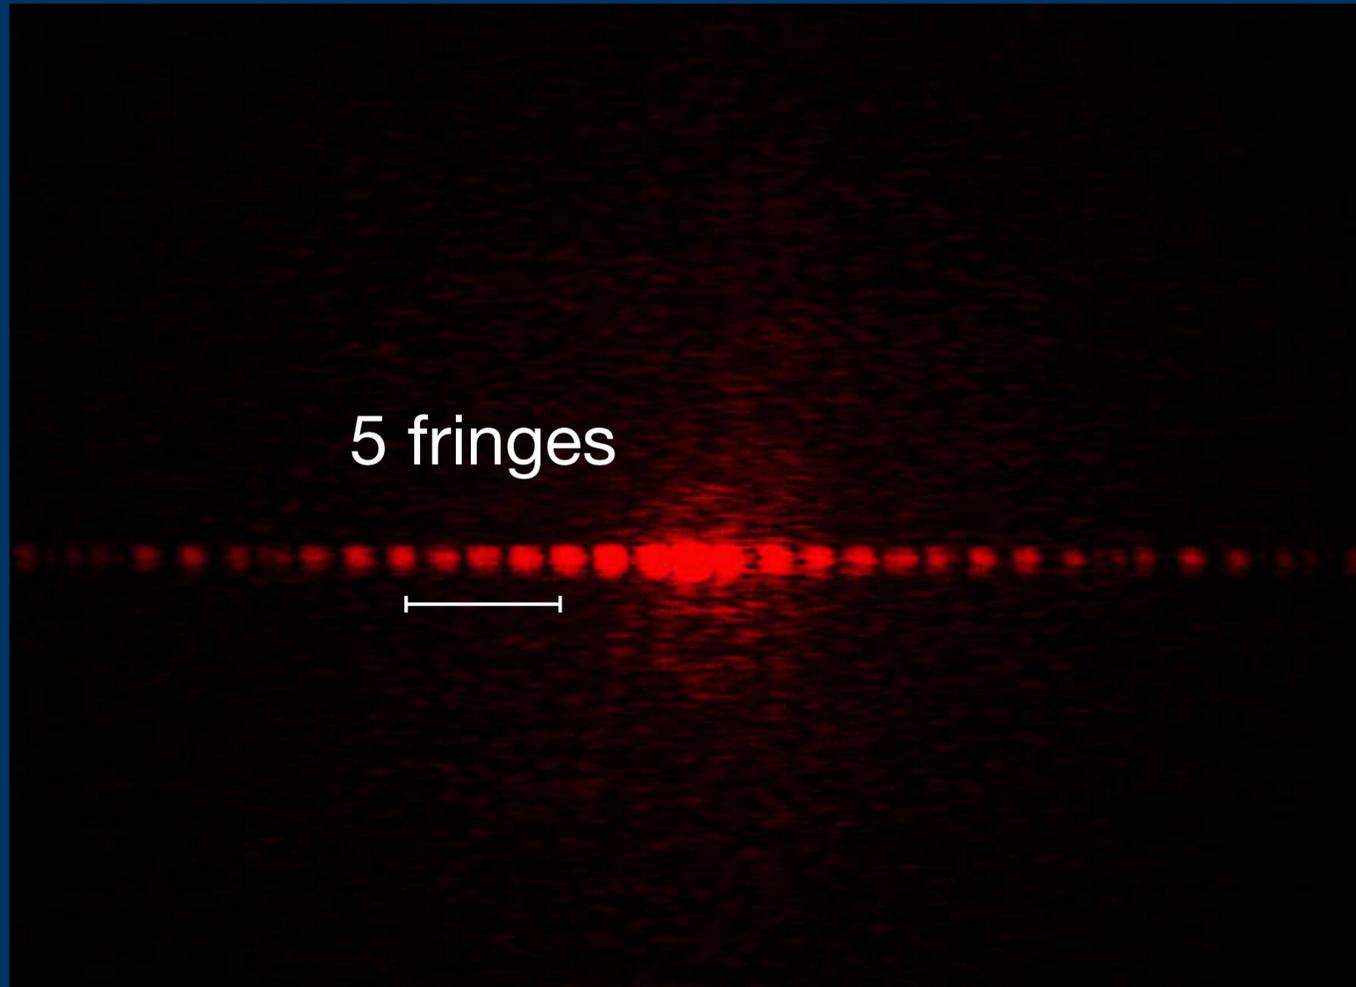

Get the fringe spacing

Gives us the wavelength of the wave

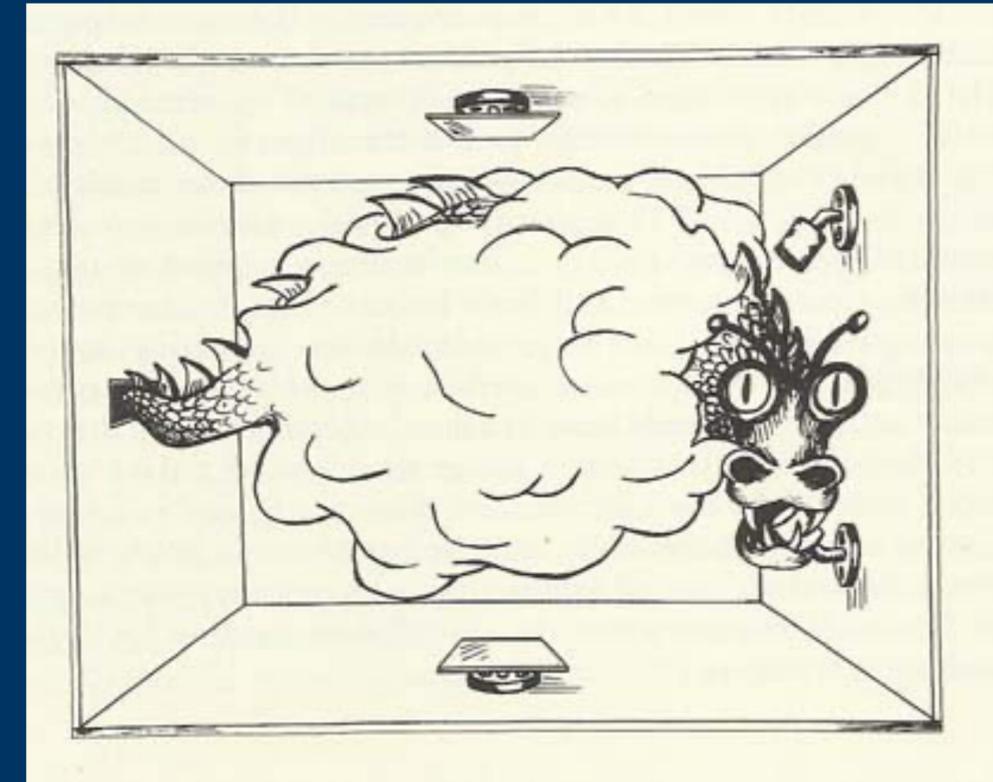

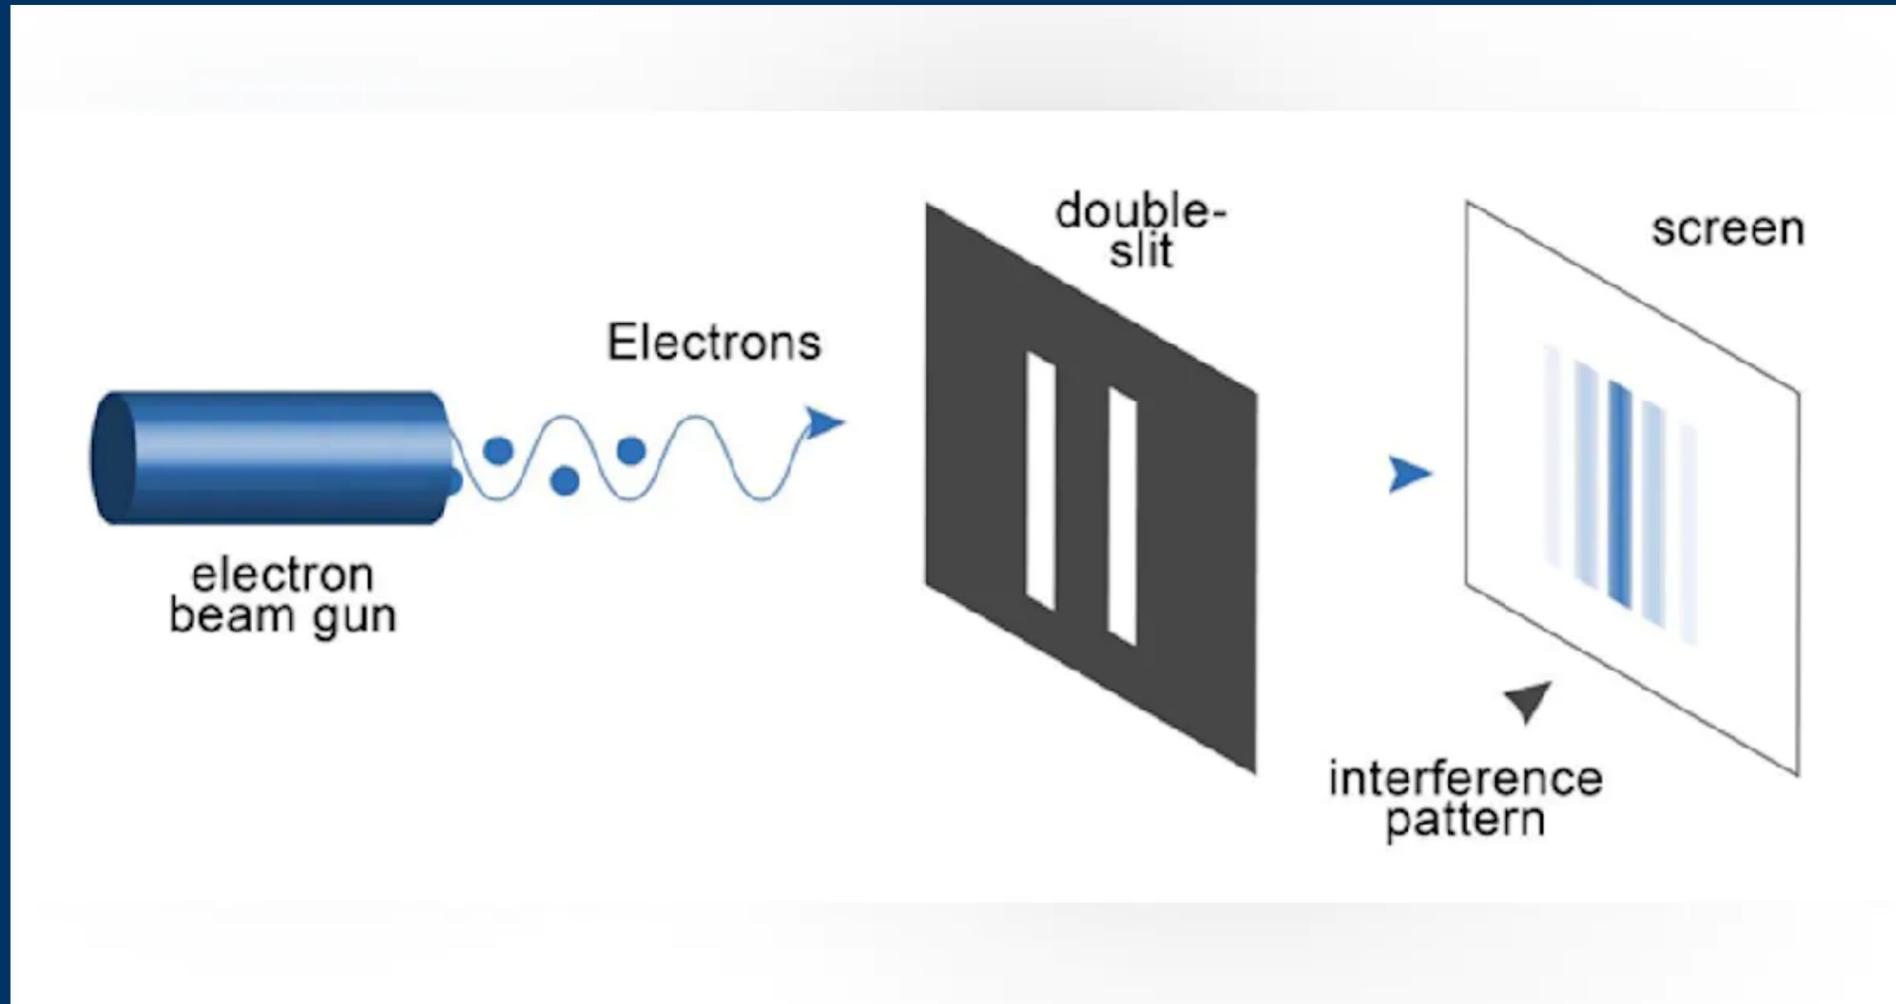

How the wavelength of light first measured...

Double slit experiment with light

That's how we could measure something so small...back in 1800s

Double slit with electrons

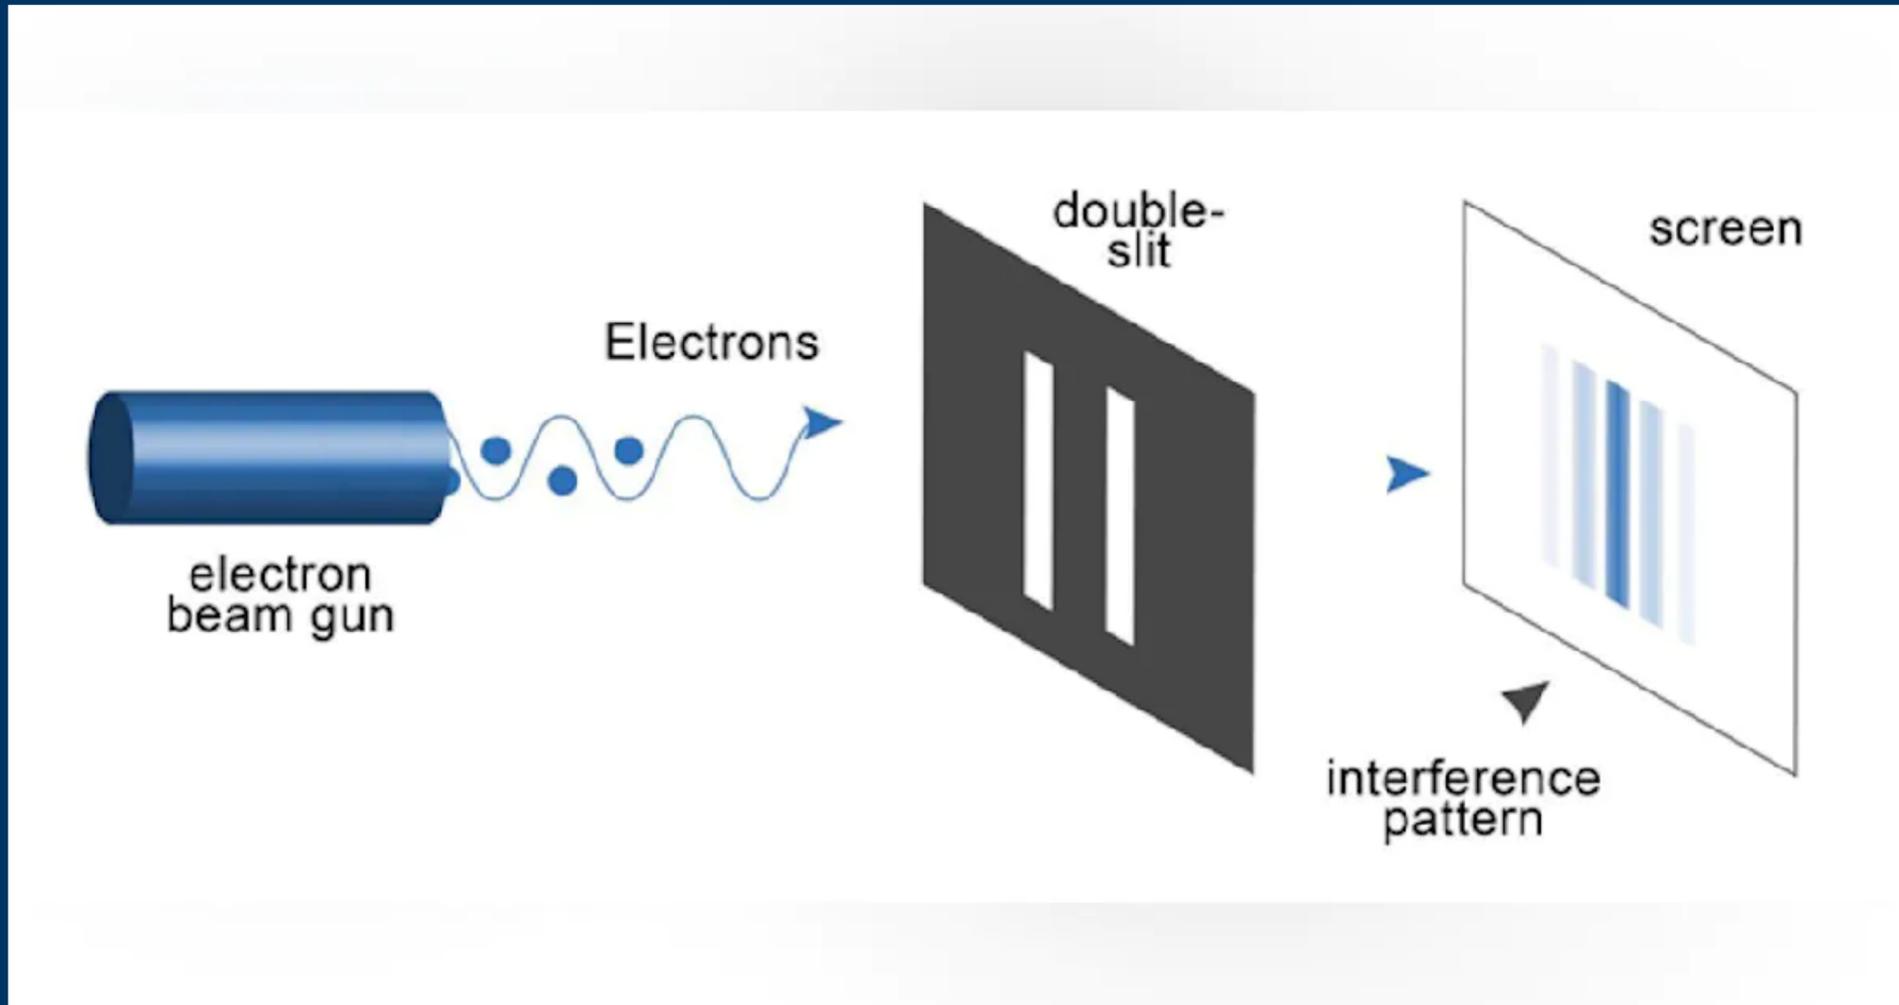

Great smoky dragon - Wheeler

Passes through the experiment as a wave

Manifests at the screen as a particle

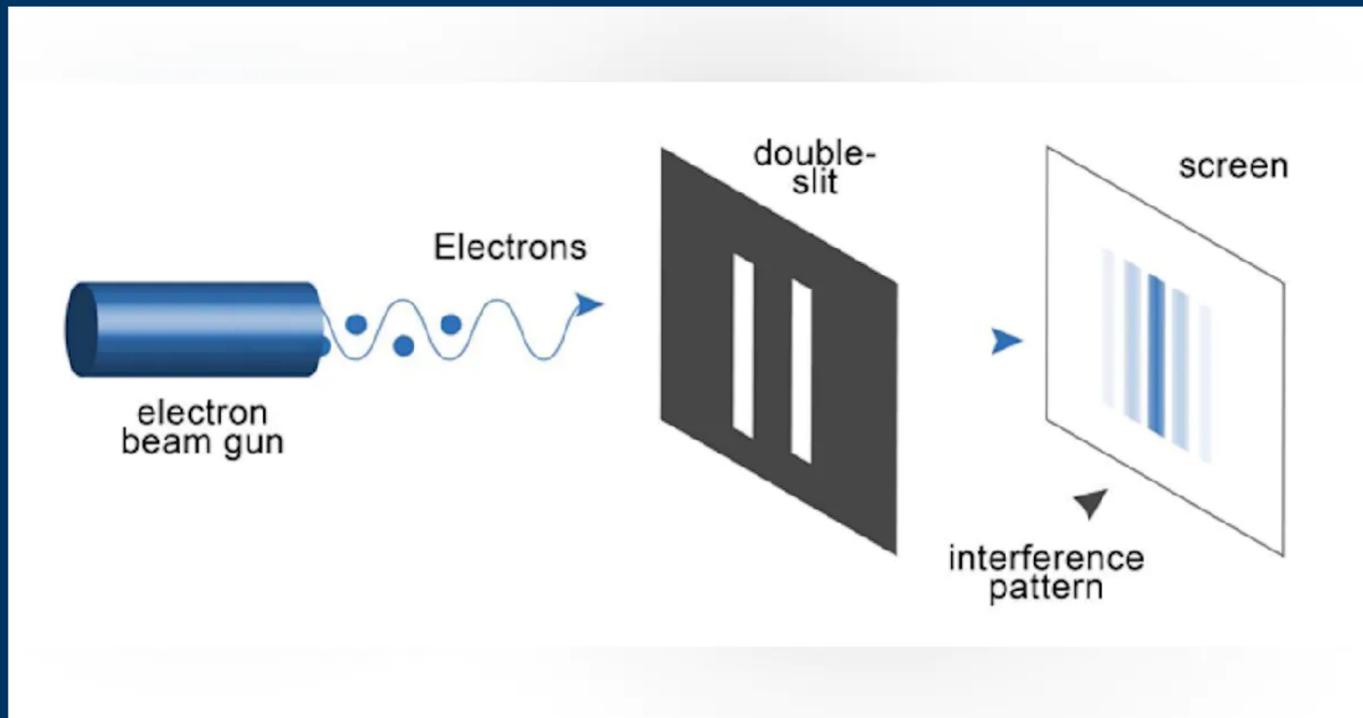

Double slit

There are no paths in QM!

How does a particle passing through one slit 'know about' the other?

So how can electrons generate interference patterns?

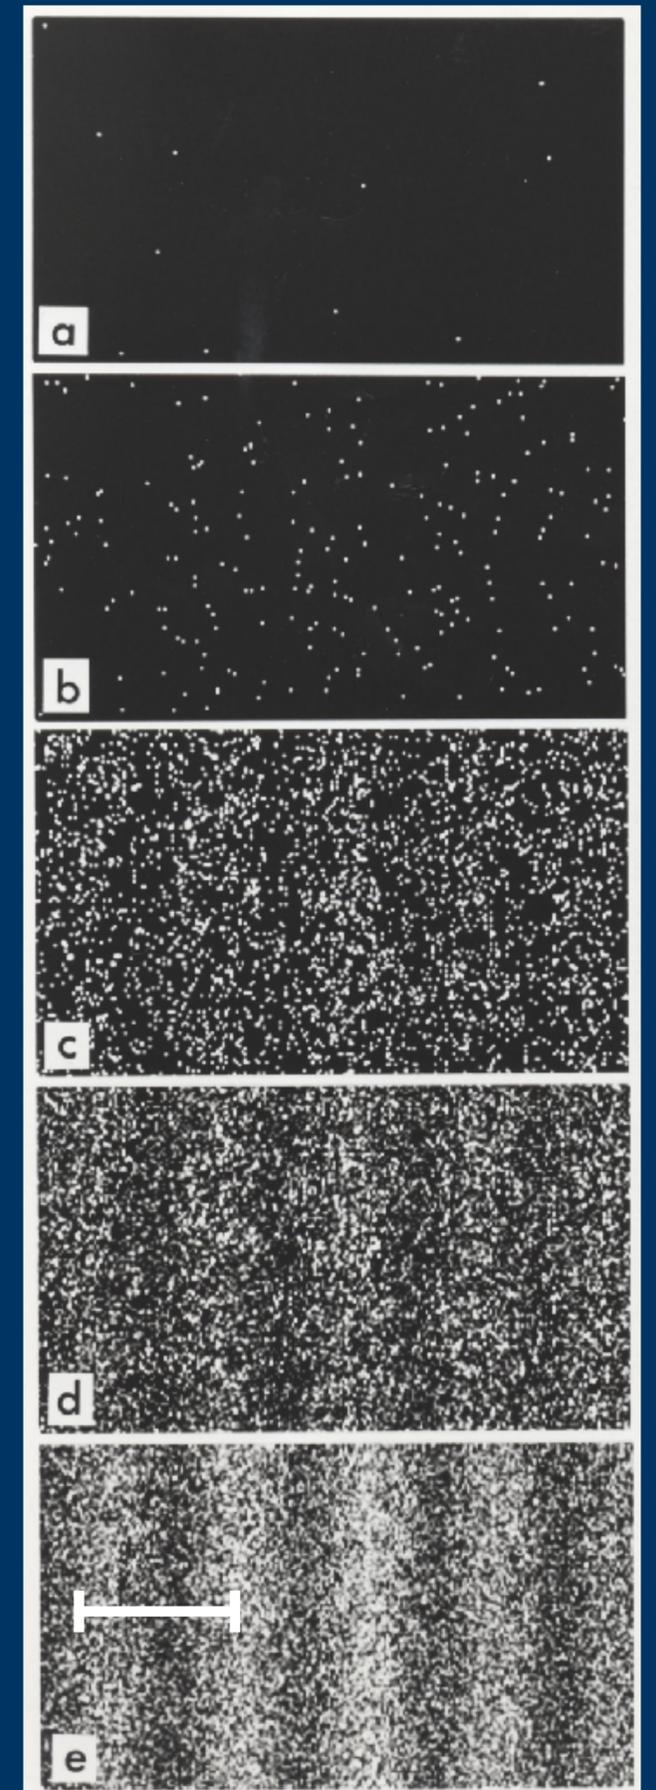

Means we can **calculate**

The 'wavelength' of the **electrons**

Turns out to be **proportional** to the **momentum** of the **particles** in the beam

Fringe spacing

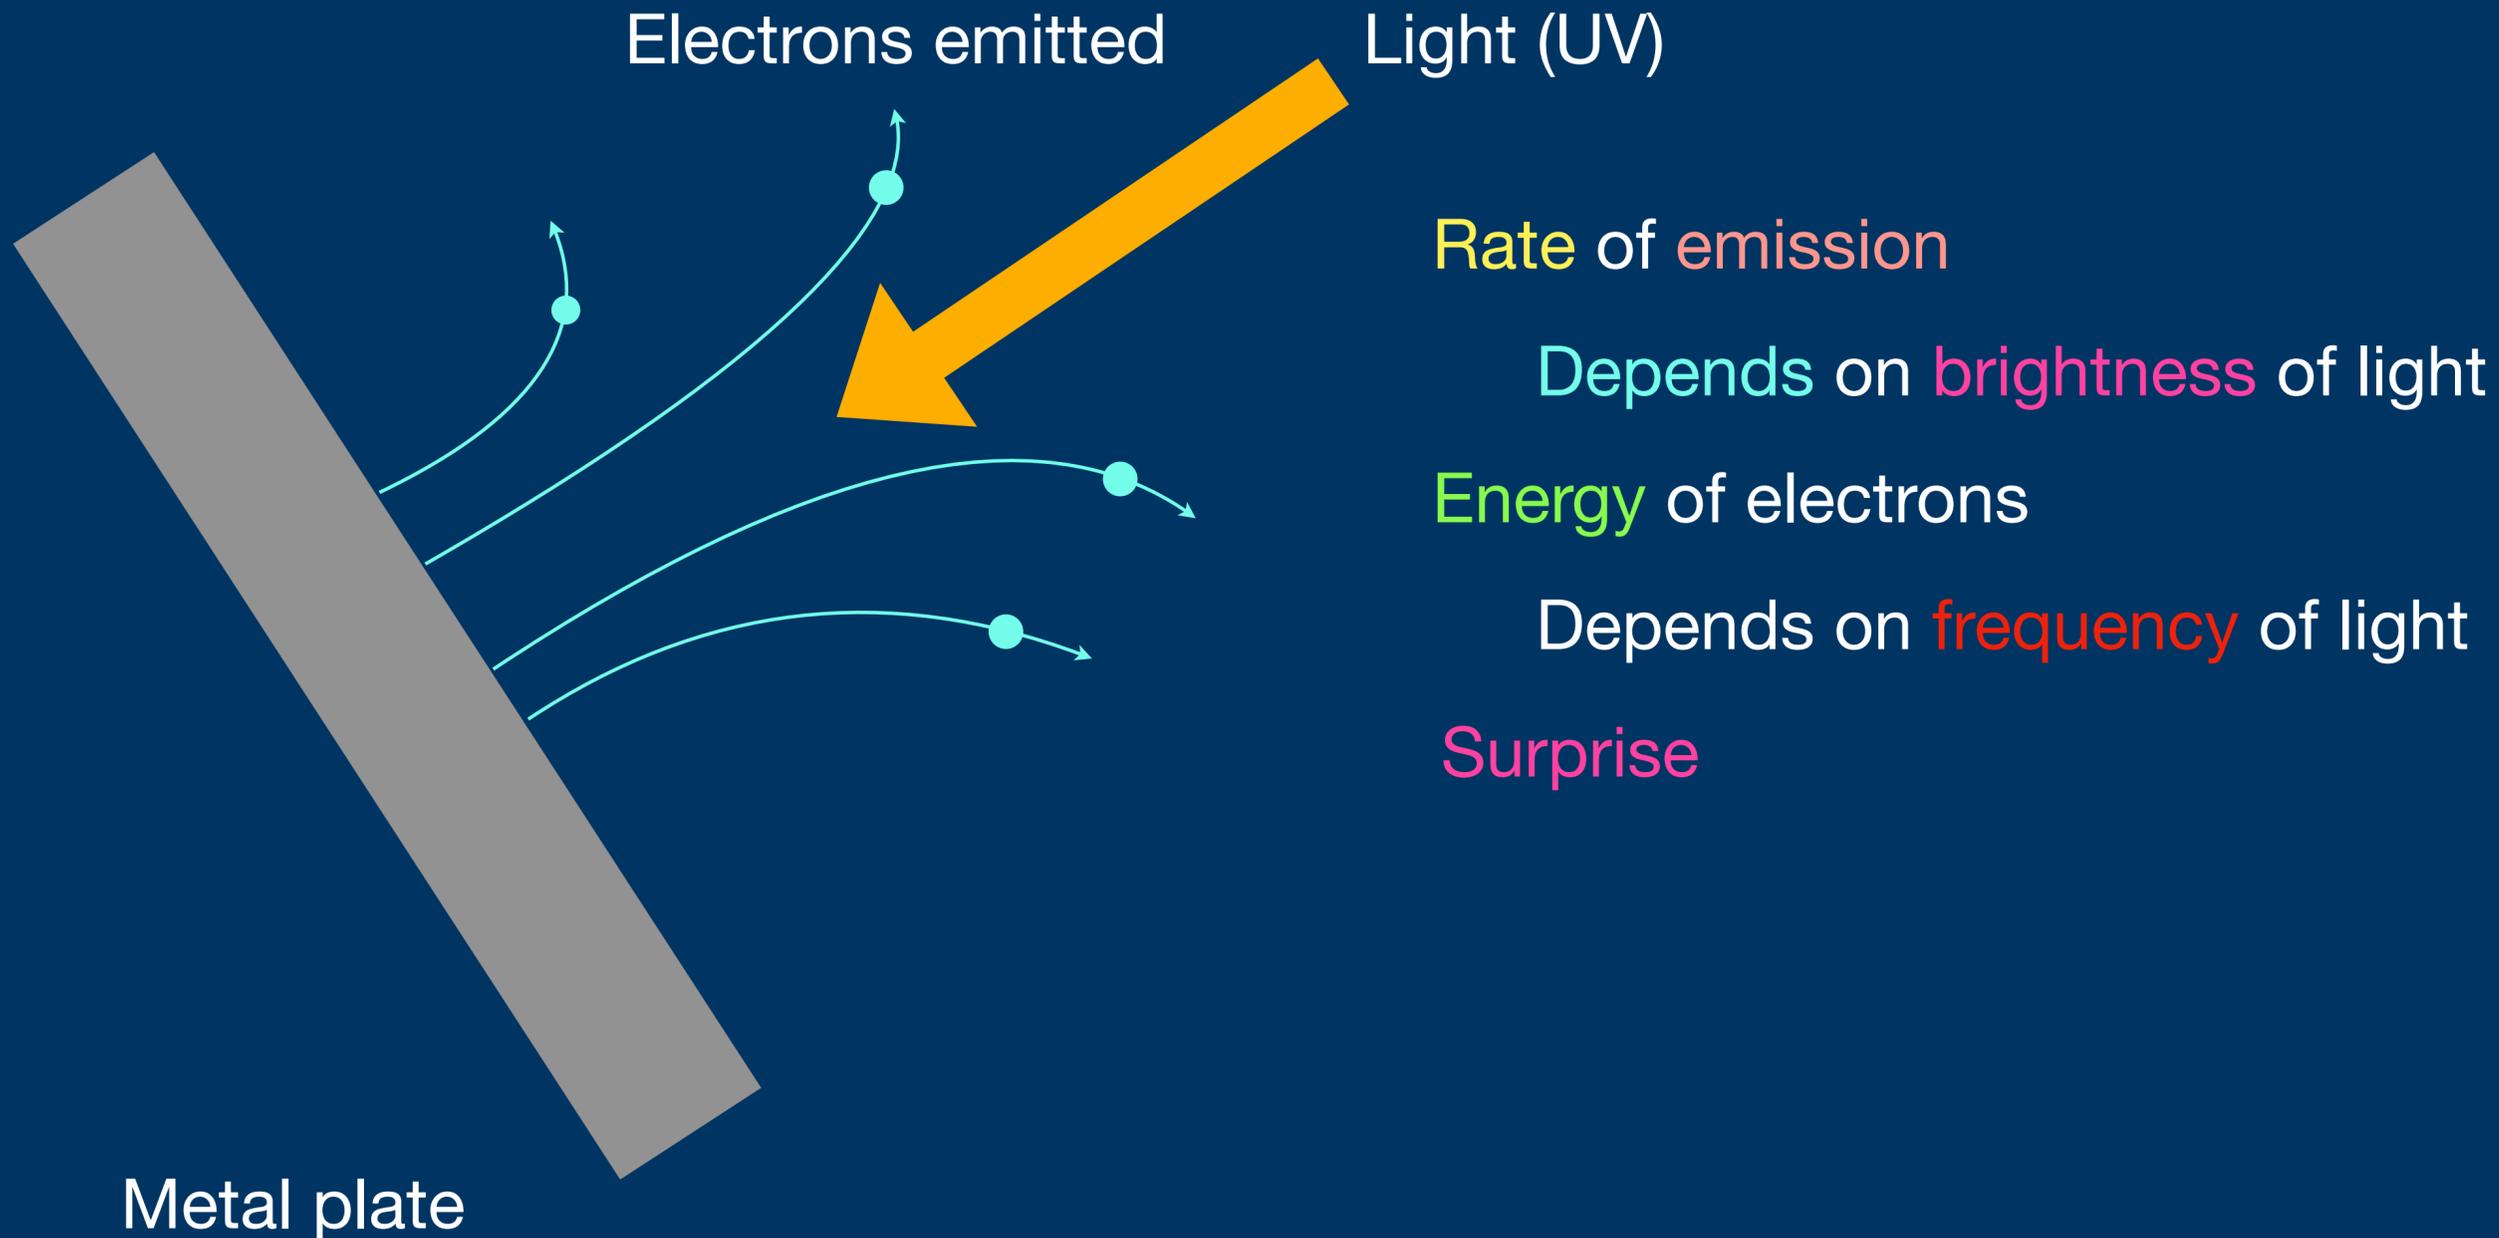

Change tack...

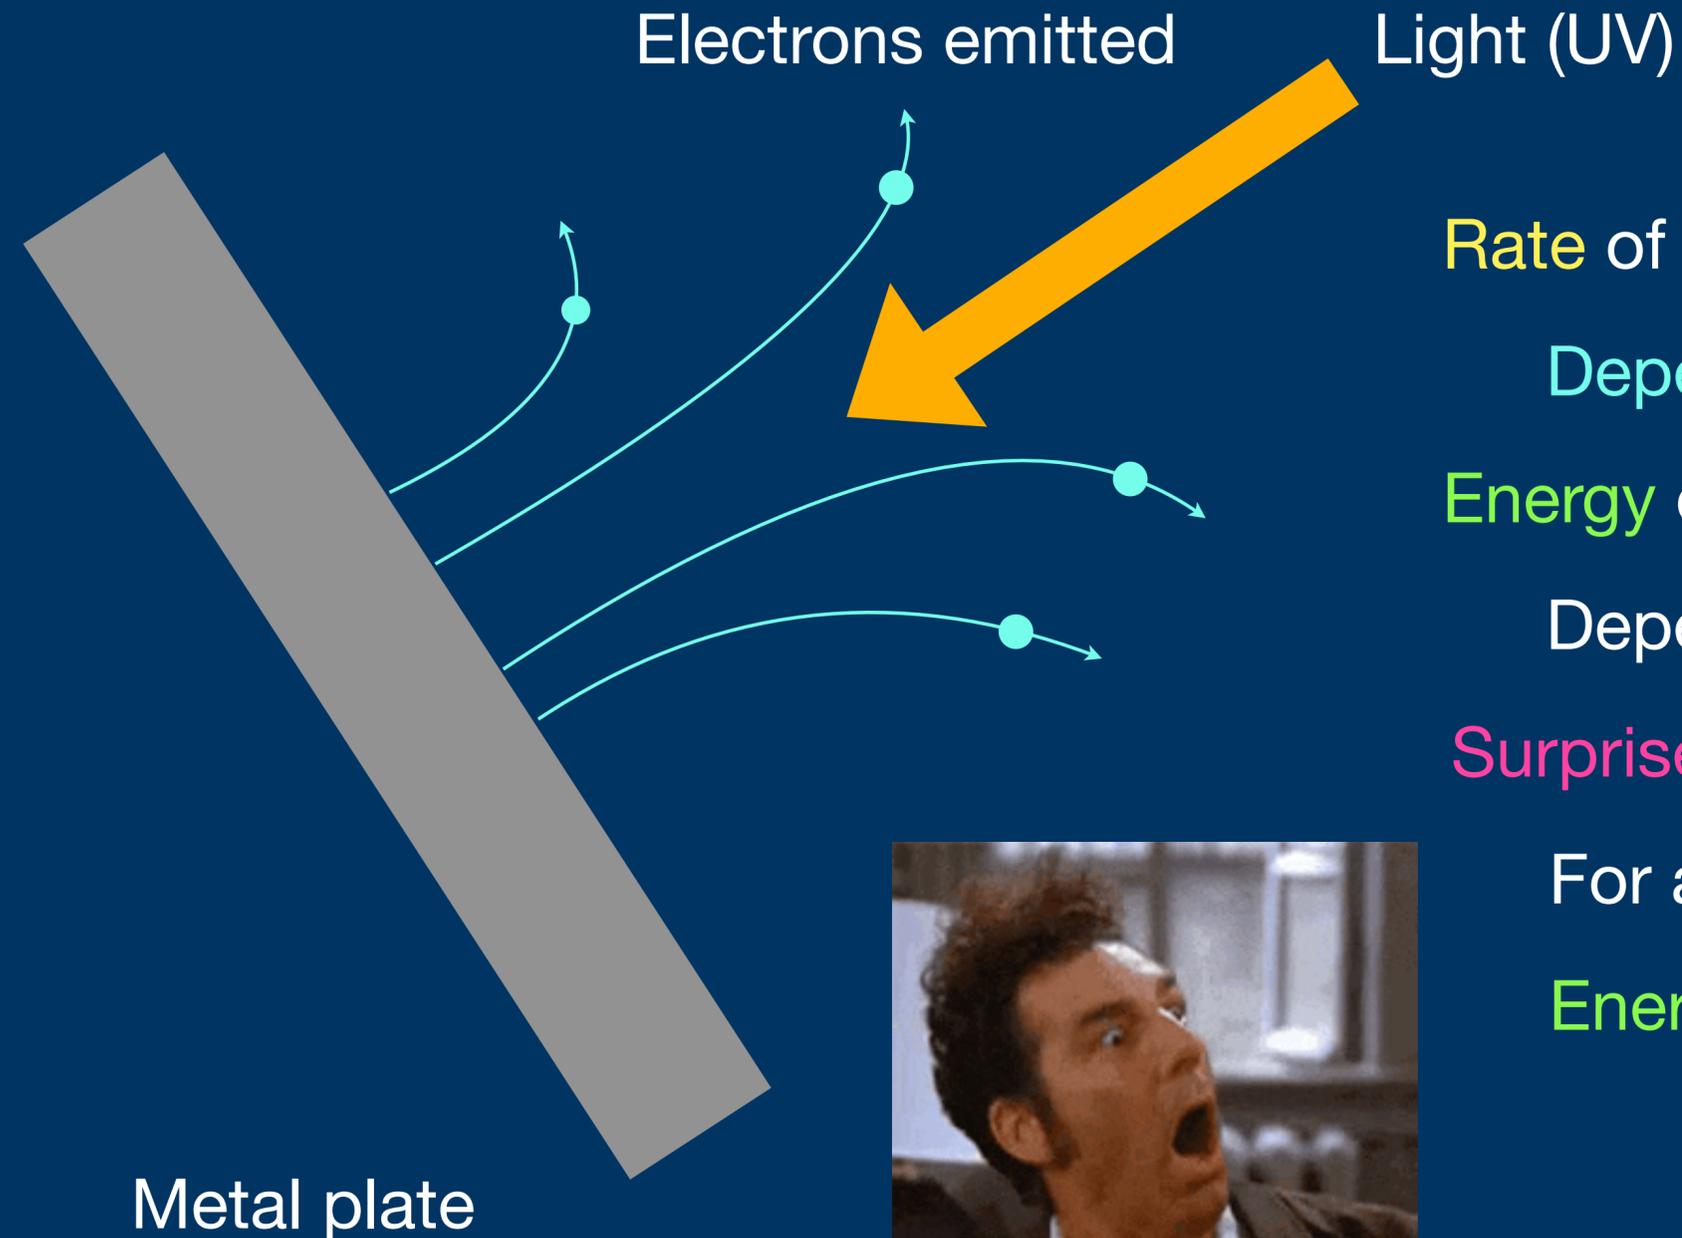

If we don't change direction soon,
we'll end up where we're going.

— *Irwin Corey* —

The photoelectric effect

The photoelectric effect

Rate of emission

Depends on brightness of light

Energy of electrons

Depends on frequency of light

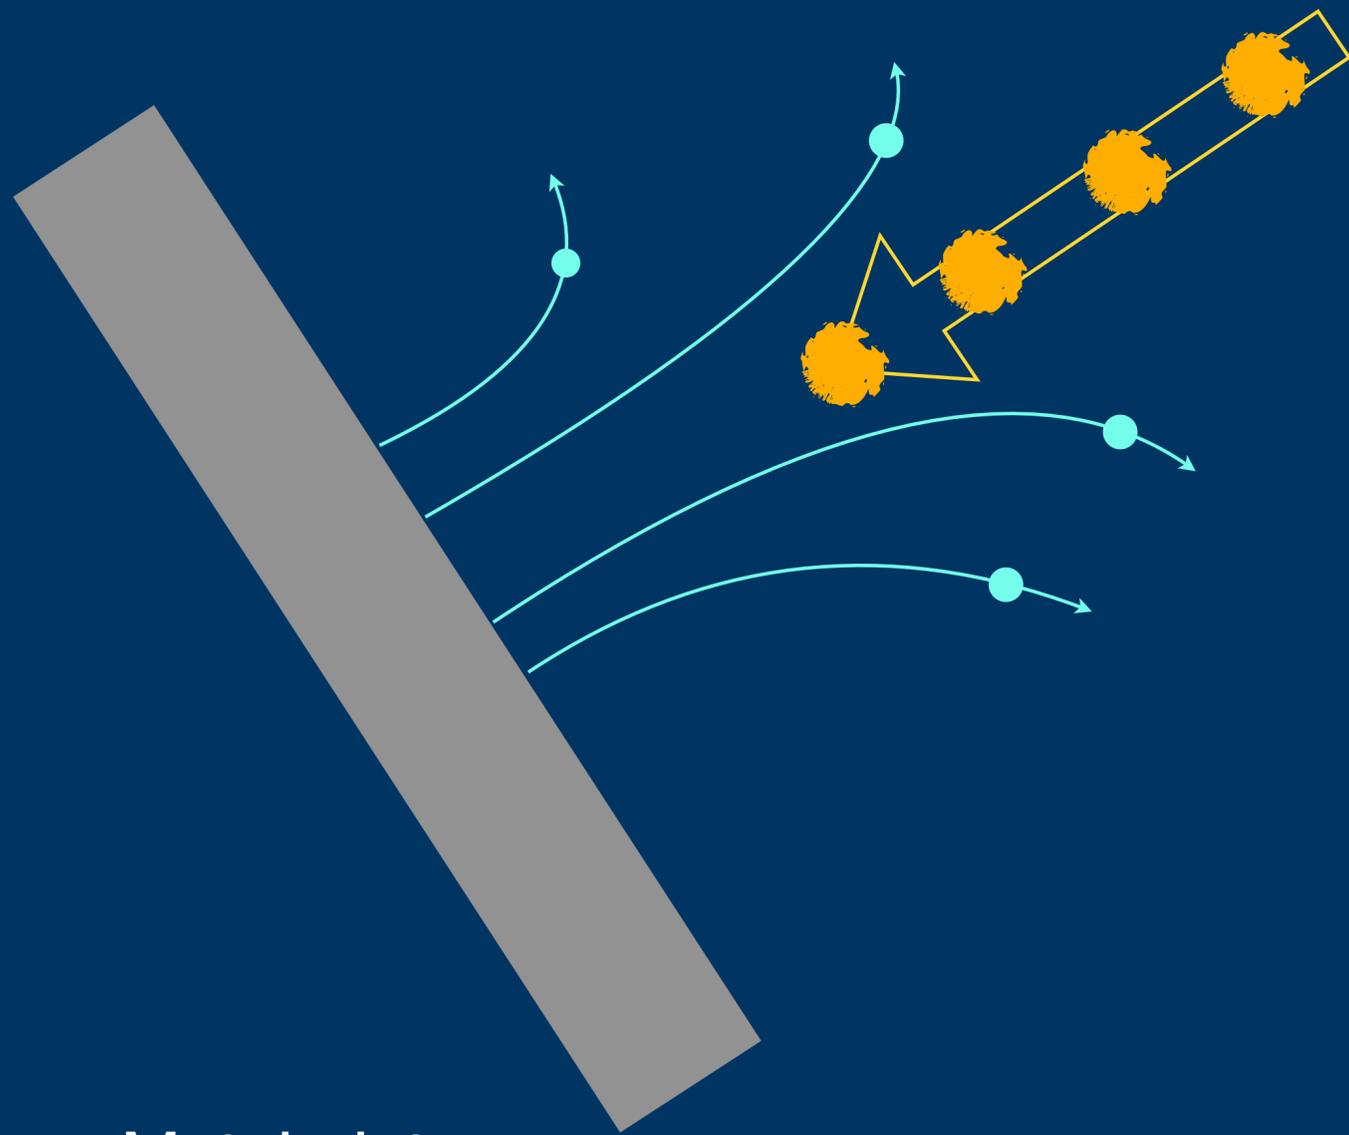

Surprise

For a wave, expect

Energy to depend on brightness

The photoelectric effect

Metal plate

Turn down the wick....
Individual photons...
Rate of emission
Drops to one electron per photon

The photoelectric effect

Metal plate

Turn down the wick....

Individual photons...

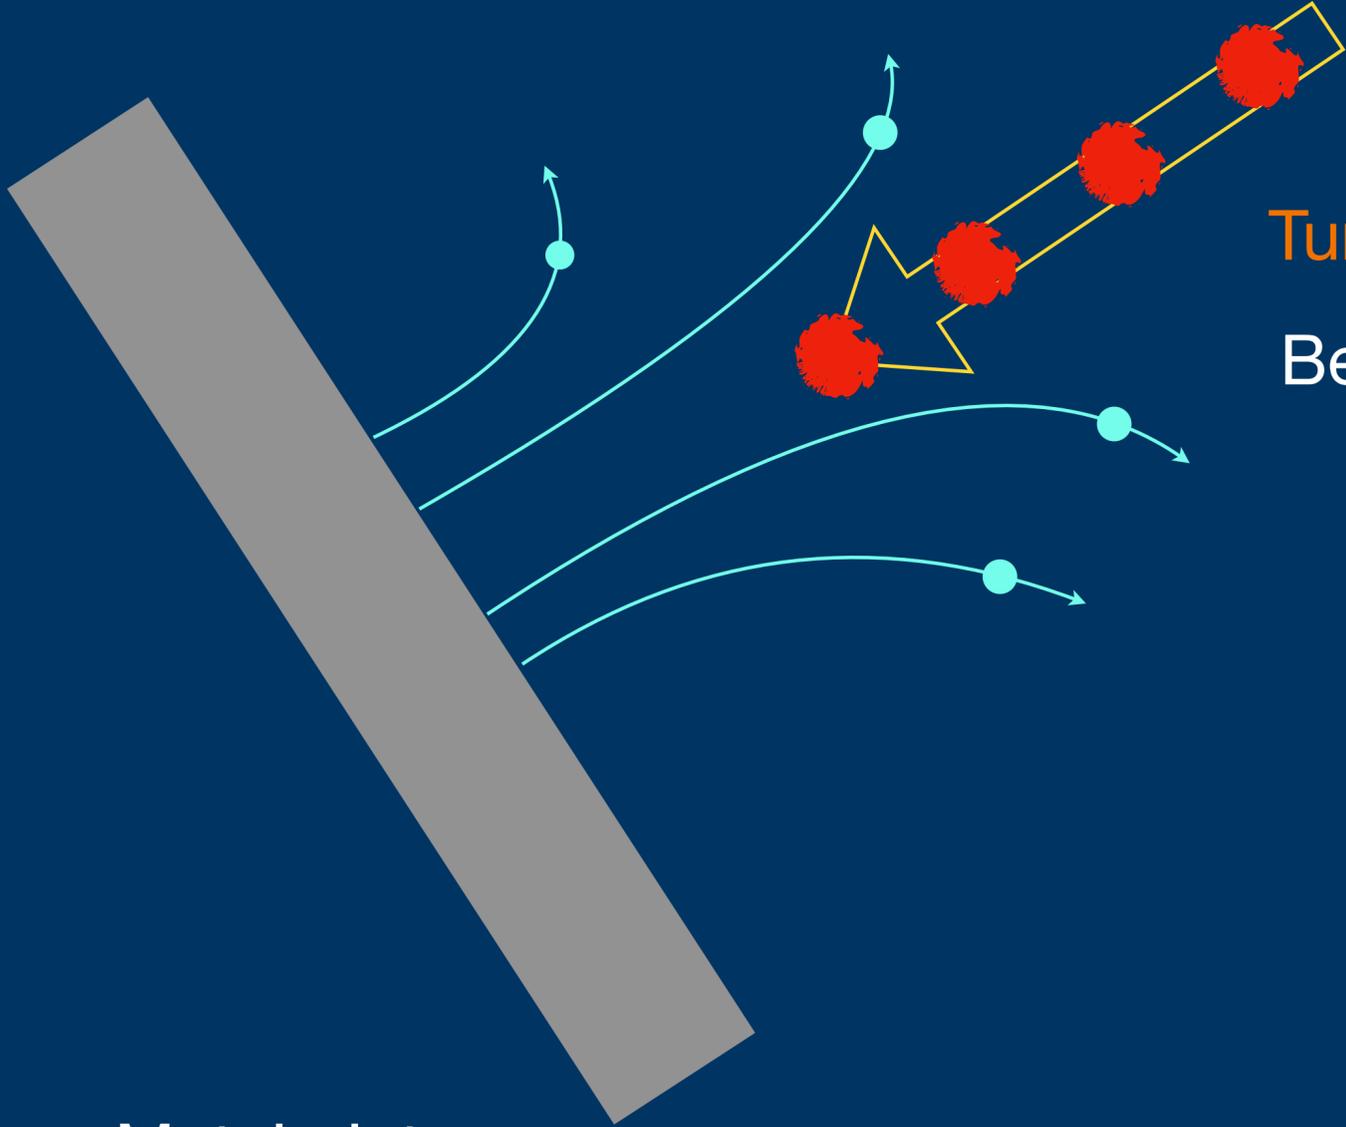

Rate of emission

Drops to one electron per photon

But all of same energy...

The photoelectric effect

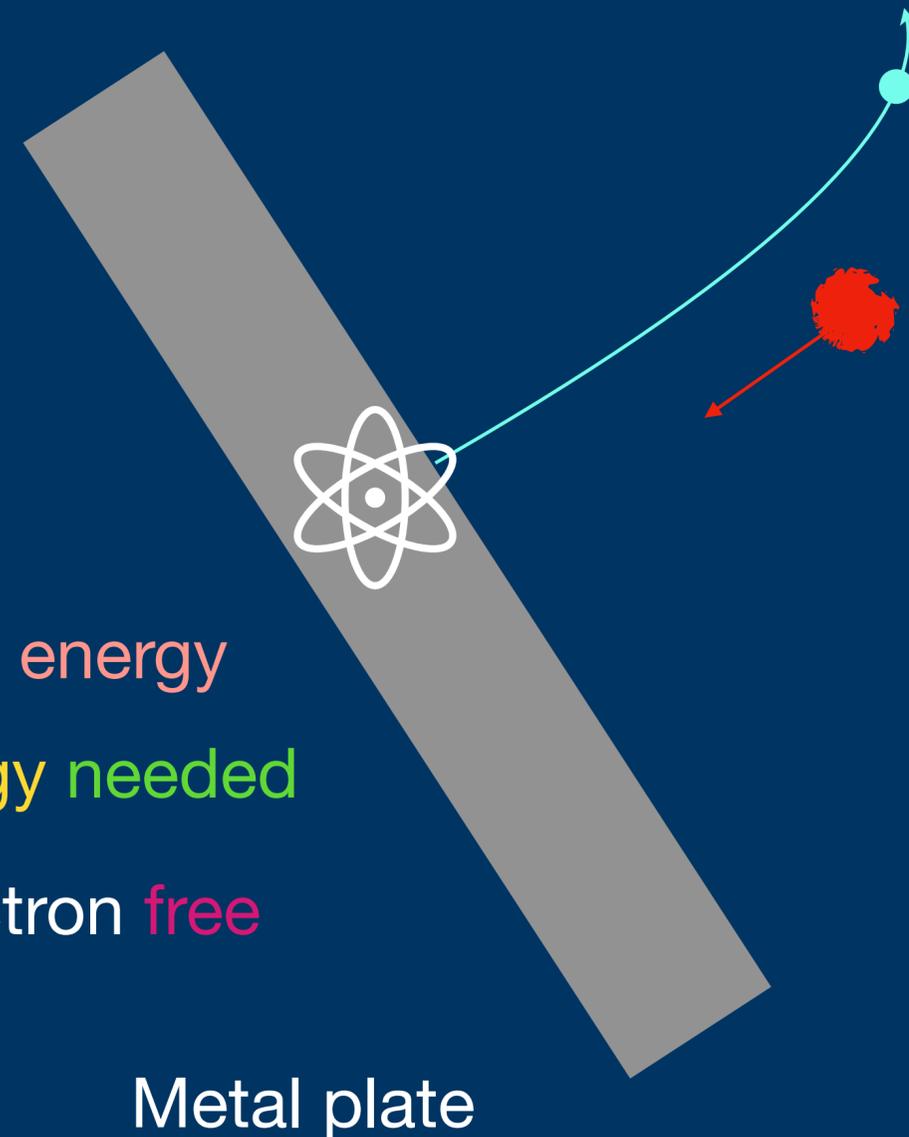

Turn down the frequency....
Below a threshold frequency

No electrons emitted

Metal plate

The photoelectric effect

Electron binding energy
Amount of energy needed
To break an electron free

Metal plate

Above frequency threshold

All emitted electrons have same energy

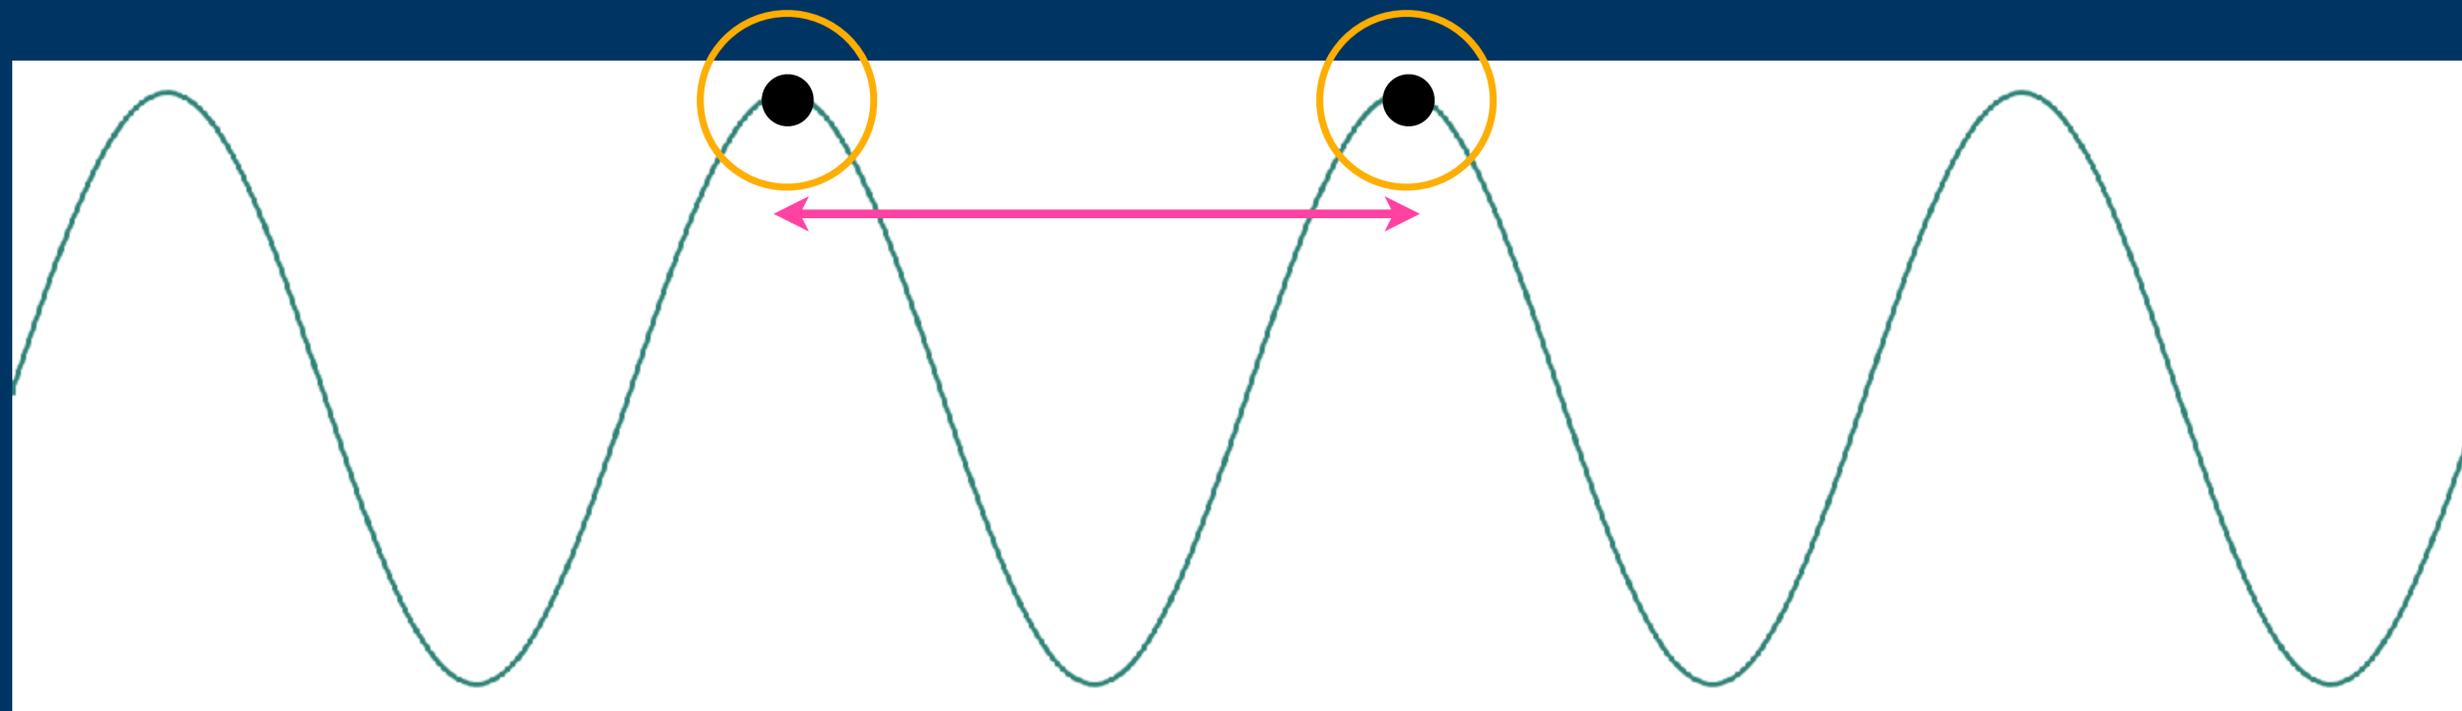

One photon breaks one electron free

Electron energy = photon energy - binding energy

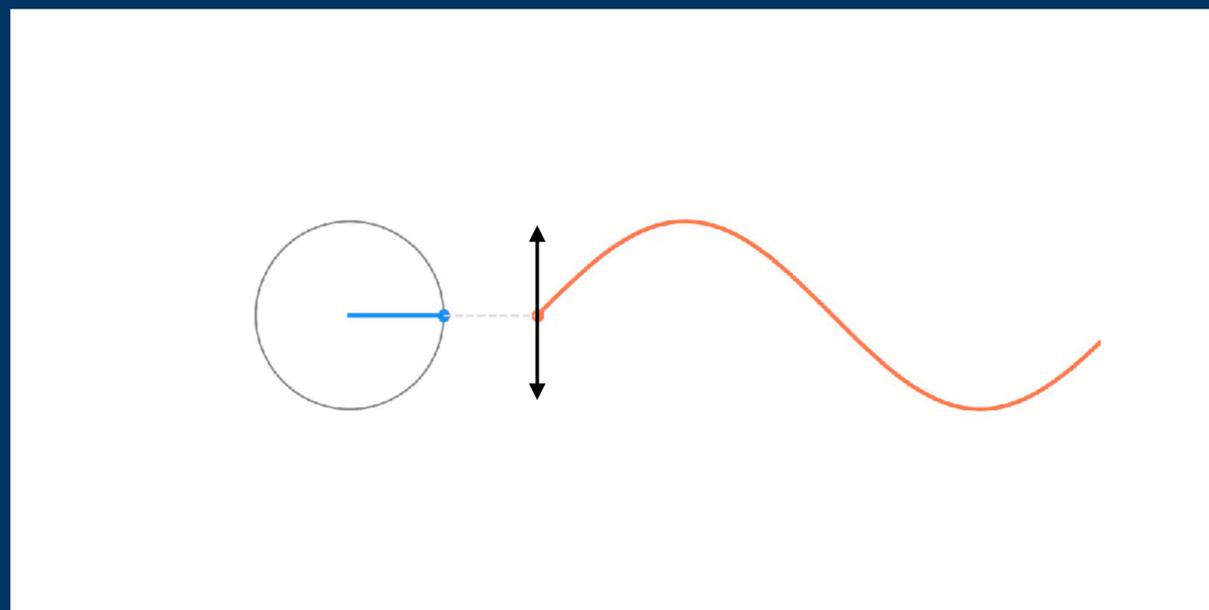

At threshold:

$0 = \text{photon energy} - \text{binding energy}$

So: photon energy depends on frequency

Wavelength \longleftrightarrow Momentum

Frequency \longleftrightarrow Energy

Schrödinger Equation

Classically, for a **particle**:

total energy = **kinetic energy** + potential energy

$$\frac{\text{momentum}^2}{2 \times \text{mass}}$$

Wave equation:

frequency aspect = $\frac{\text{wavelength aspect}^2}{2 \times \text{mass}}$ + potential energy

$$i\hbar \frac{\partial \psi}{\partial t} = - \frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} + V\psi$$

ψ Wave function

But...

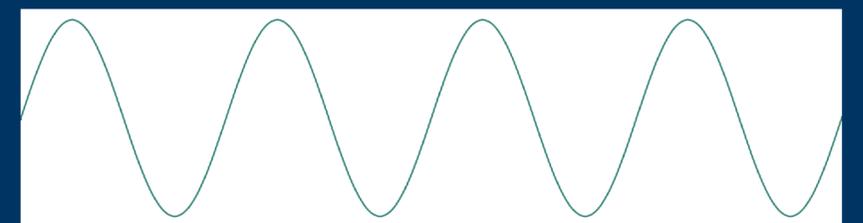

frequency aspect = $\frac{\text{wavelength aspect}^2}{2 \times \text{mass}}$ + potential energy

$$i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} + V\psi$$

ψ Wave function

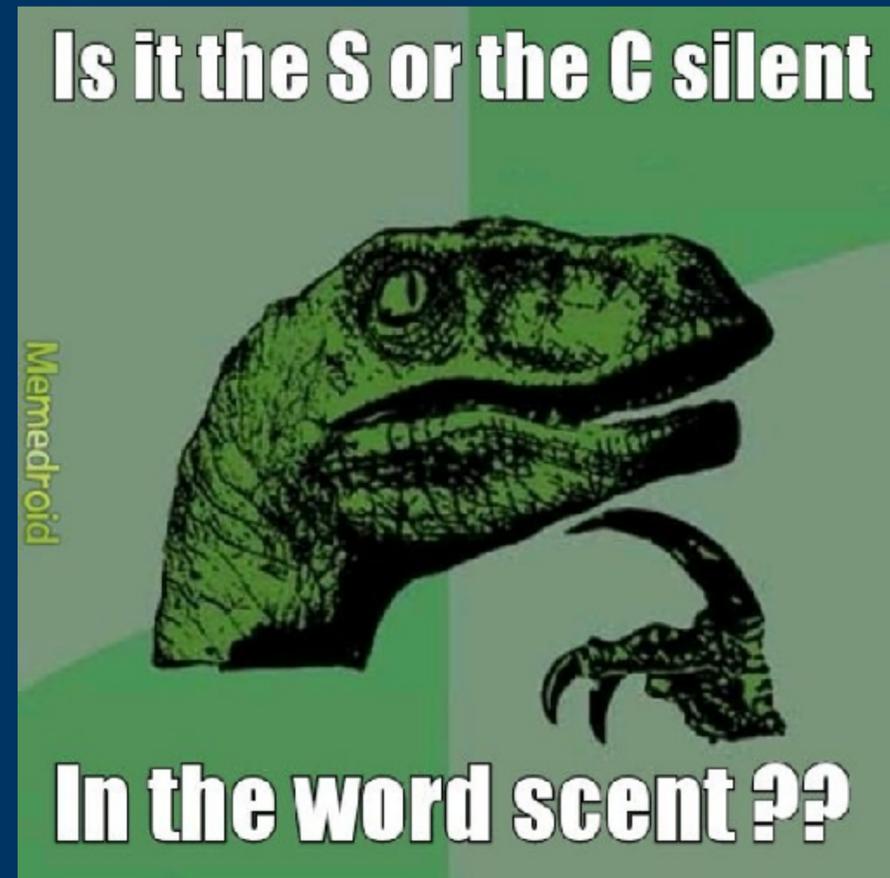

Not always in the form of a 'wave'

As we would recognise it...

Leaves the big question...

What is it that's waving?????

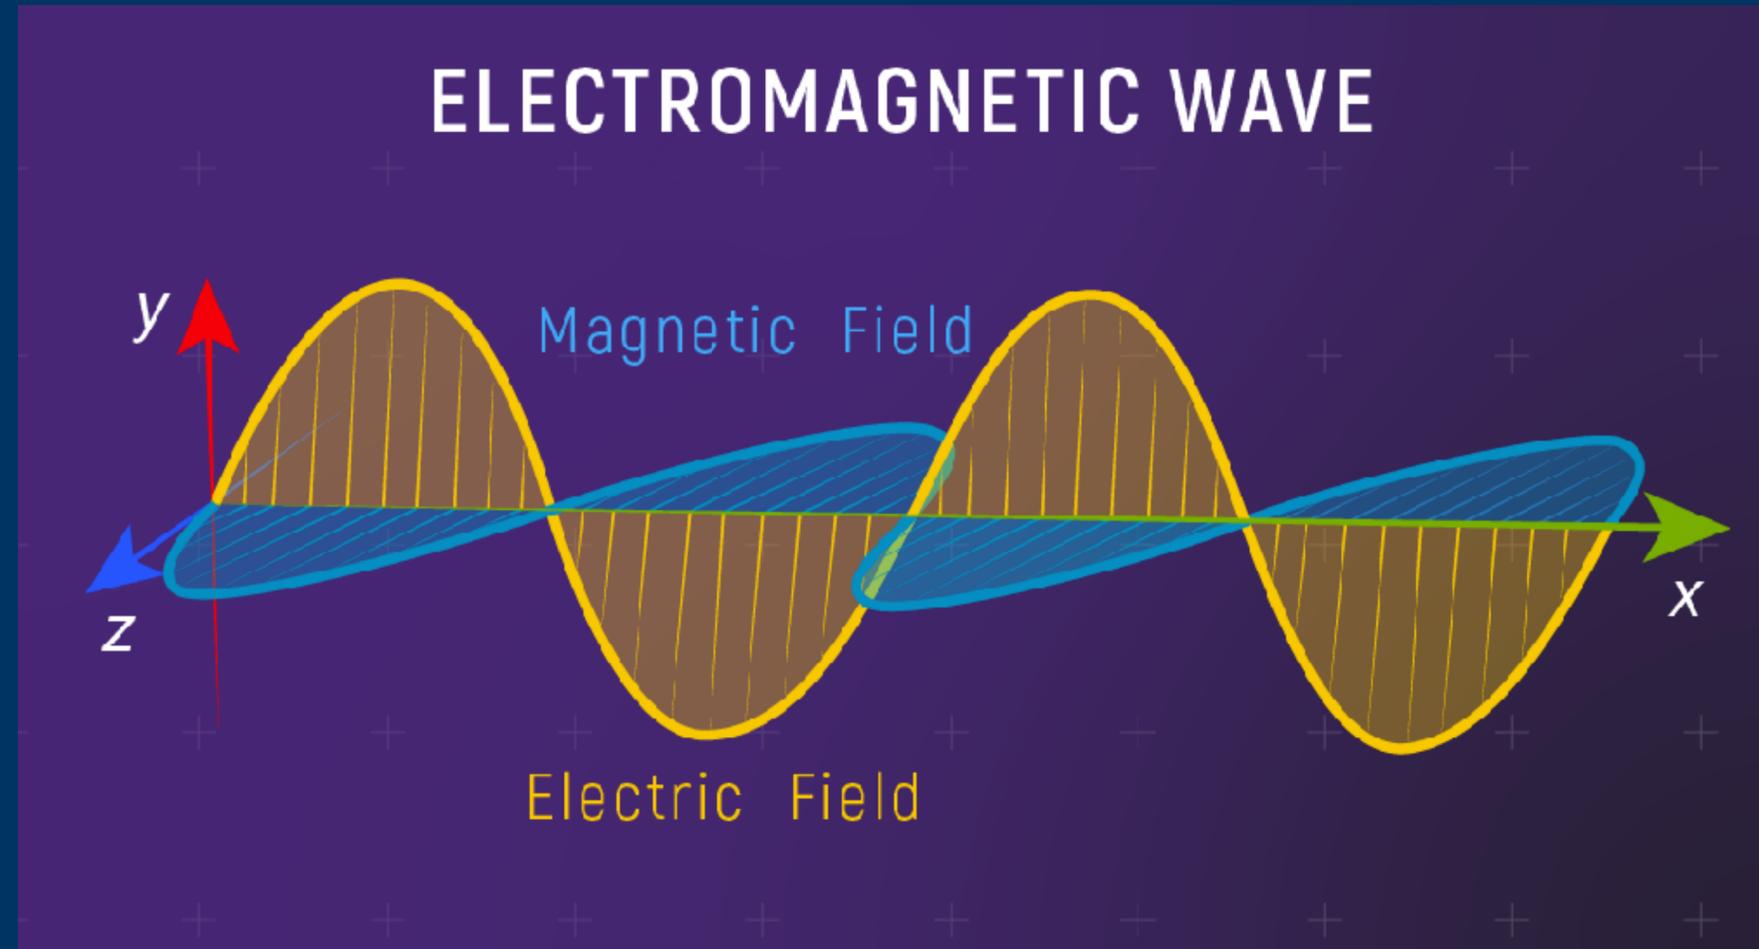

Light

An **electromagnetic** wave

Is **physical**

Just not **tangible**...

Variations in **electric** and **magnetic** fields

Health warning: the magnetic aspect is much weaker than shown here...

The wave function

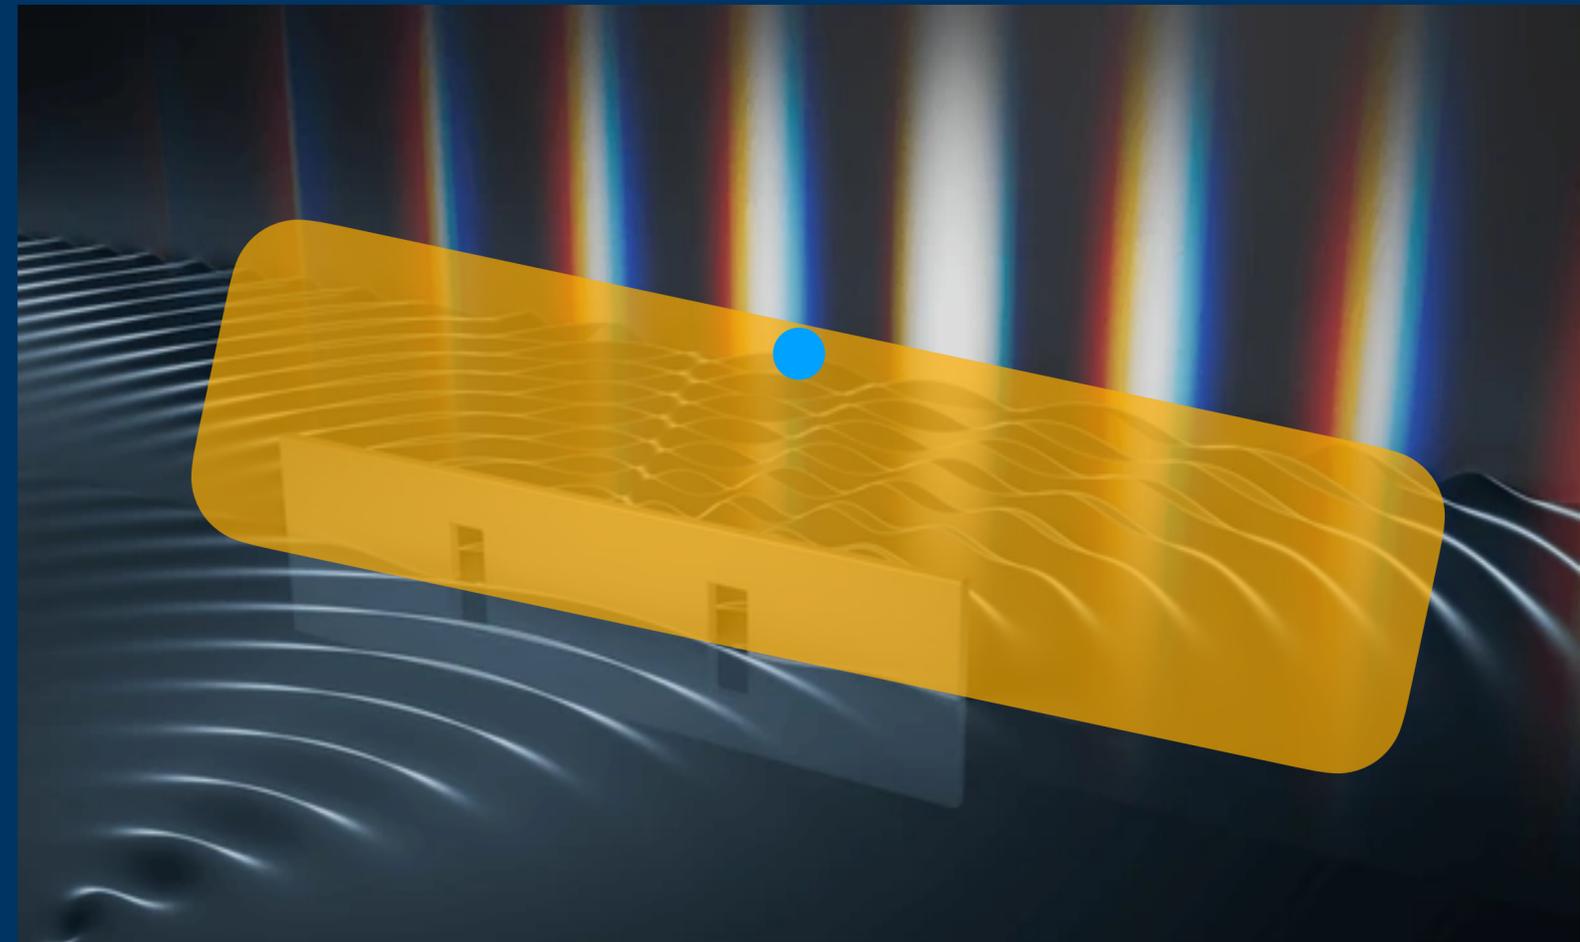

Is **not** in any sense 'physical'

The **intensity** cannot be **measured**

If the **electron** 'was' the **wave function**

Detect a 'spread out' **region of charge**

Detect a tiny '**dot**' of charge **instead**

Quantum physics: is discovered
Every physicist when it was discovered:

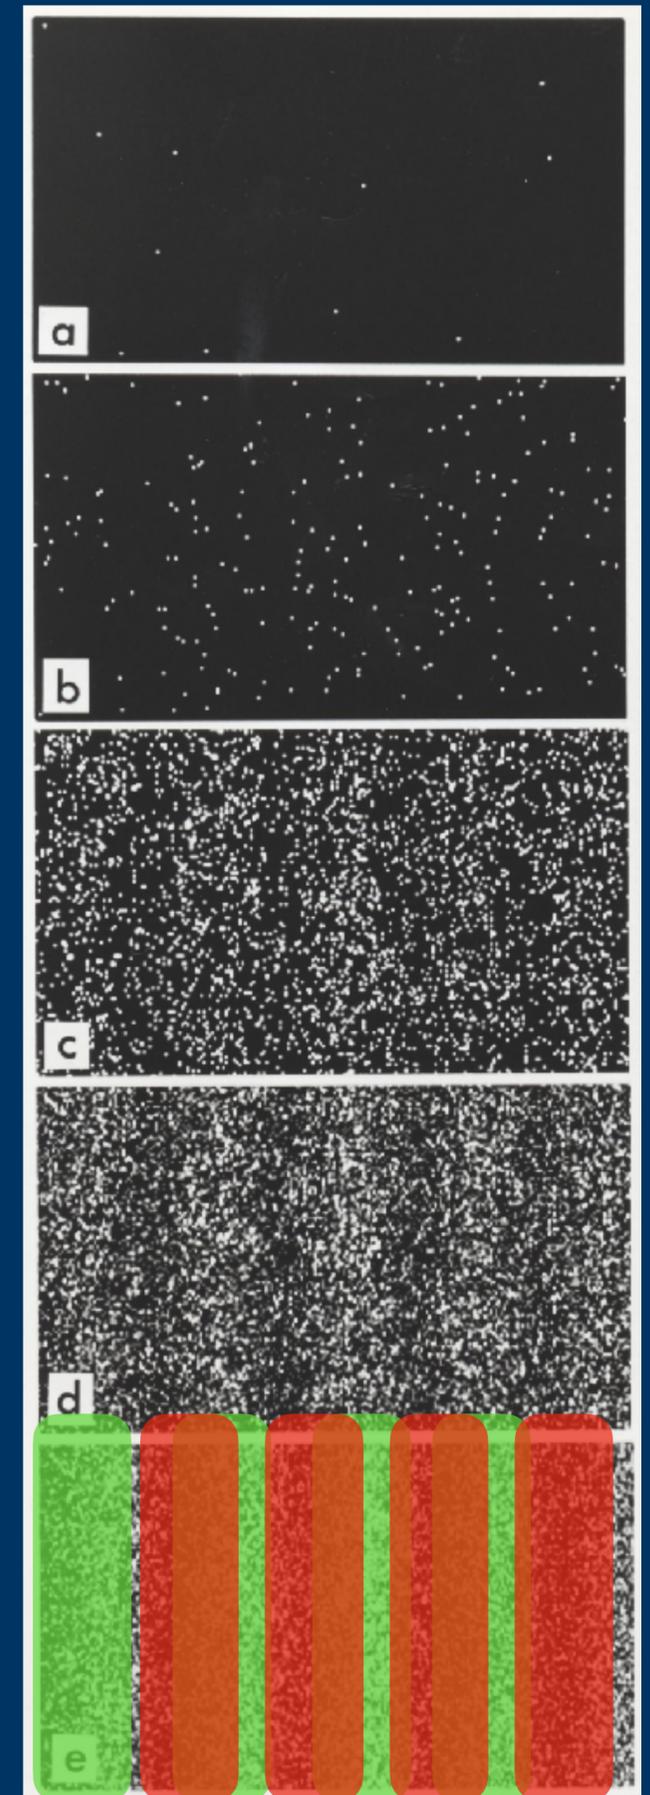

The wave function

Where the wave is more intense

More likely that an electron will turn up

Where the wave is less intense

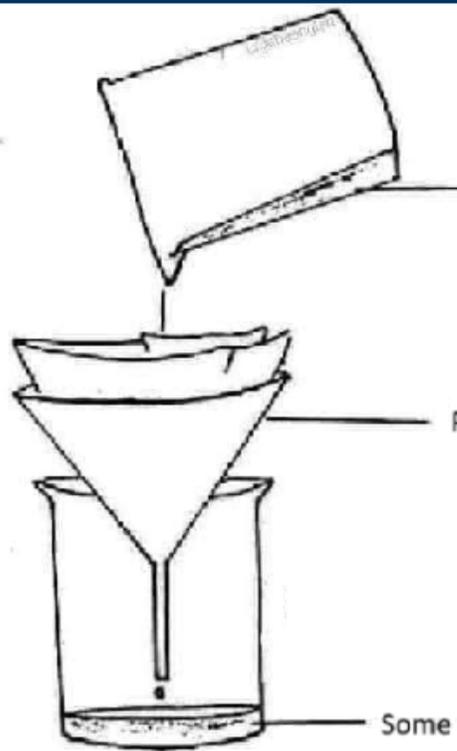

Less likely that an electron will turn up

Humanity's collective understanding of quantum mechanics gained through the hard work of generations of scientists, mathematicians, and philosophers since its discovery over 100 years ago.

Popular media

Some cat that's both alive and dead

Its a probability wave...

Whatever that means...

What is probability anyway?

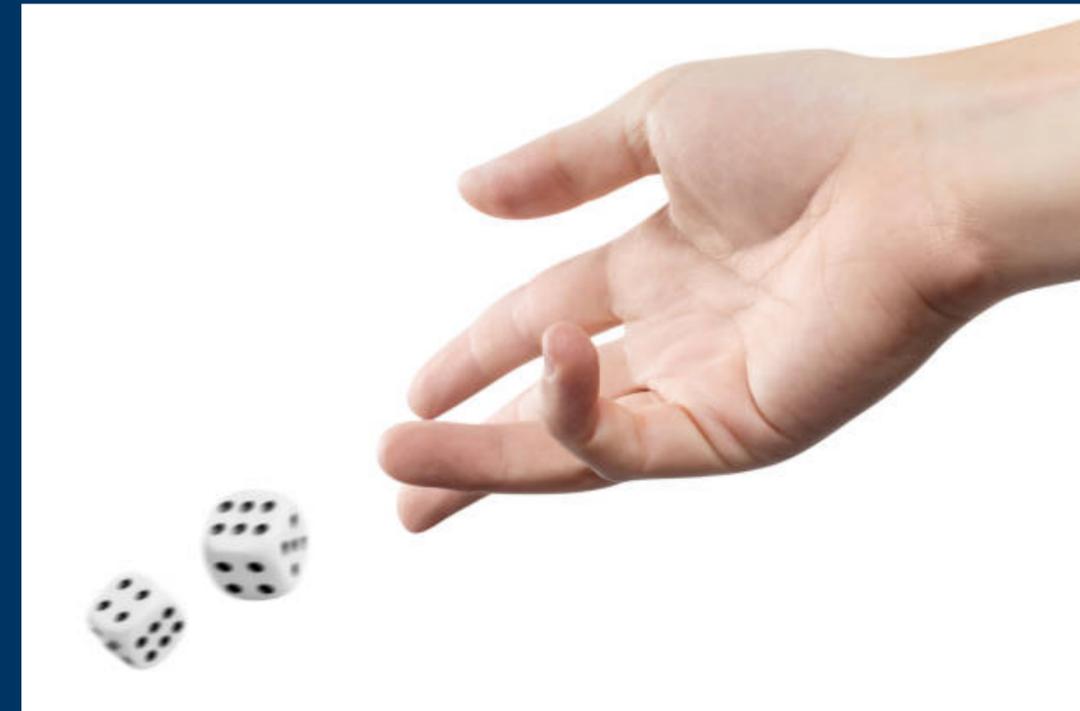

Examples:

Throwing a **dice**:

1 in 6 for **any side**

As there are **6 faces**

The **probability** is 'physical'

FOUR-SIDED DICE

remarkably easy to find with your bare feet in the dark

What is probability anyway?

Examples:

Horse race

Probability of a win...

More of an estimate

Charitable....more of a guess...

But physical - horse, running, other competitors...

What is probability anyway?

Examples:

Molecular speeds

Gas at a **temperature**

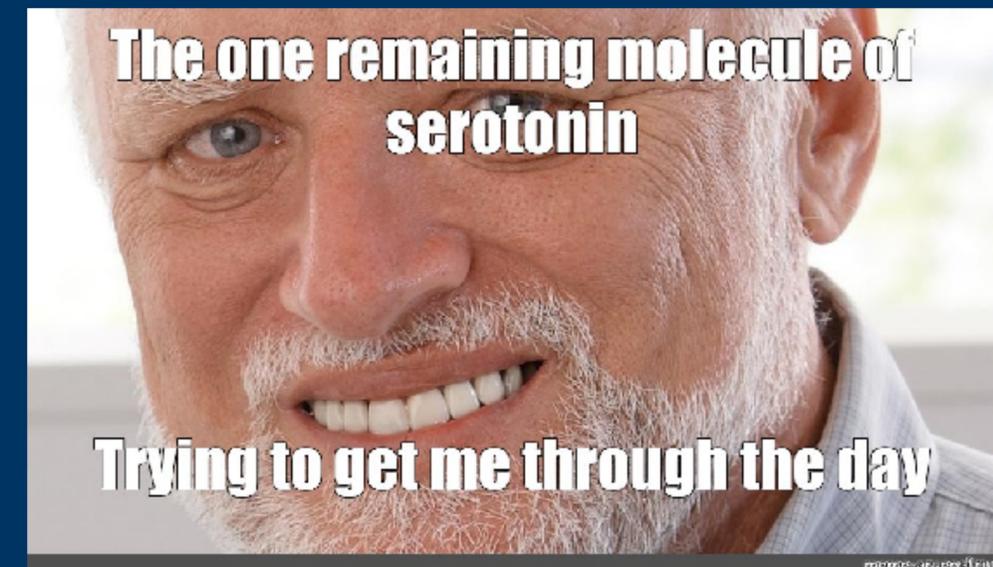

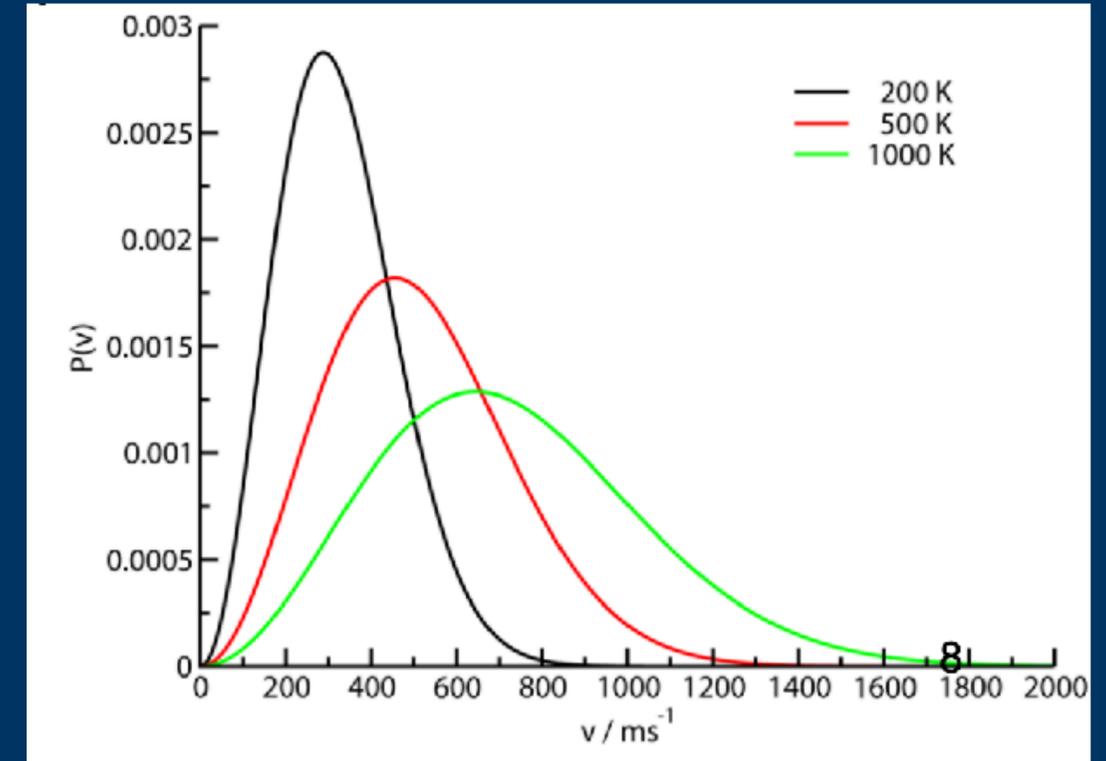

Contains **molecules** at **different speeds**

Can **calculate** the **distribution**

Does **not** tell you the **speed** of a **molecule**

Tells you the **chance** of **picking** one out with a **certain speed**

Still arguably **'physical'**

What is probability anyway?

Examples:

Wave function

Probability of finding a particle at a certain place

Probability of the field manifesting a particle at that place

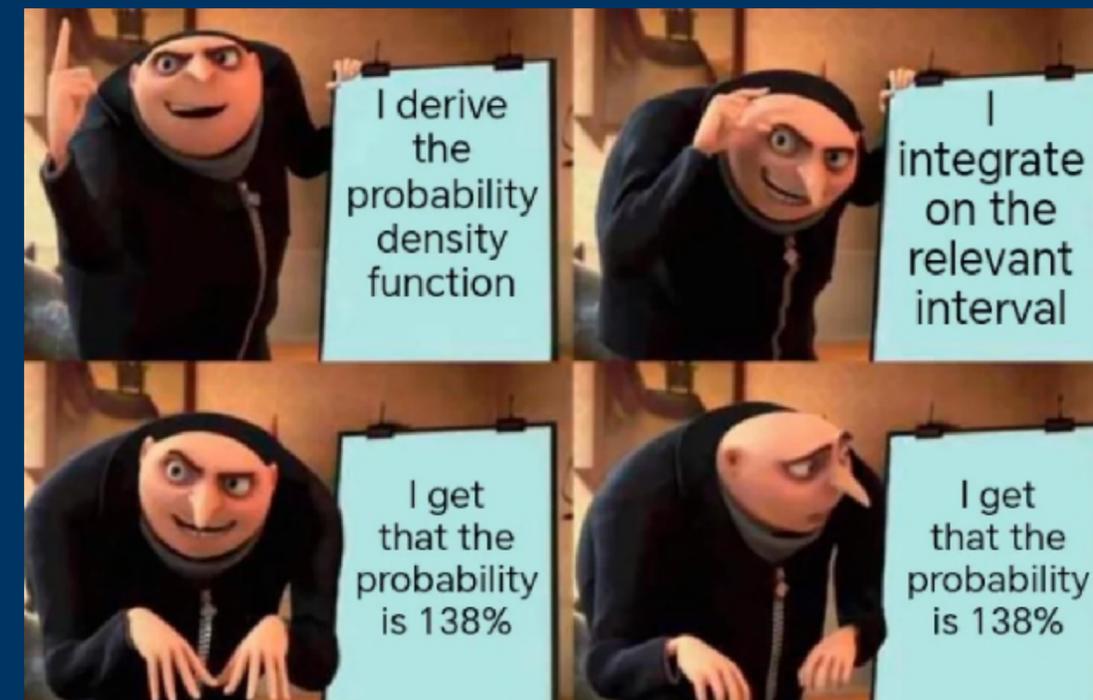

Works for a single particle...

Single particle interference

In what way is it physical???

Hidden variable distribution???

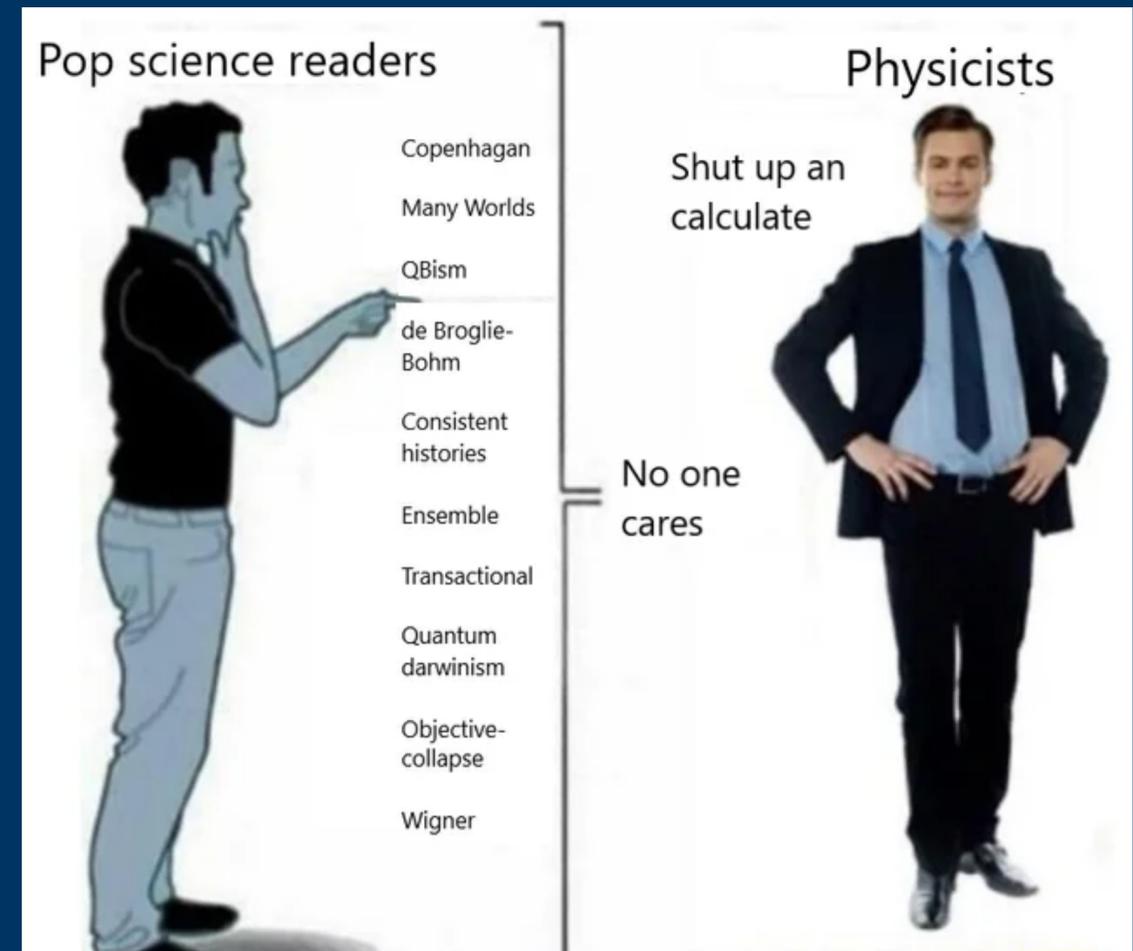

Local hidden variables ruled out

Big interpretive issue...

What is the **wave function** representing?

What is a **quantum probability**???

Heisenberg

the possibility or ‘tendency’ for an event to take place has a kind of reality—a certain intermediate layer of reality, halfway between the massive reality of matter and the intellectual reality of the idea or the image—this concept plays a decisive role in Aristotle’s philosophy.

In modern quantum theory this concept takes on a new form; it is formulated quantitatively as probability and subjected to mathematically expressible laws of nature.

Stuart Kauffman

We thus propose a new kind of ontological duality as an alternative to the dualism of Descartes: *in addition to res extensa, we suggest, with Heisenberg, what may be called res potentia.* We will argue that *admitting the concept of potentia into our ontology is fruitful,* in that it can *provide an account of the otherwise mysterious nonlocal phenomena of quantum physics* and at least three other related mysteries ('wave function collapse'; loss of interference on which-way information; 'null measurement'), without requiring any change to the theory itself.

Change tack...

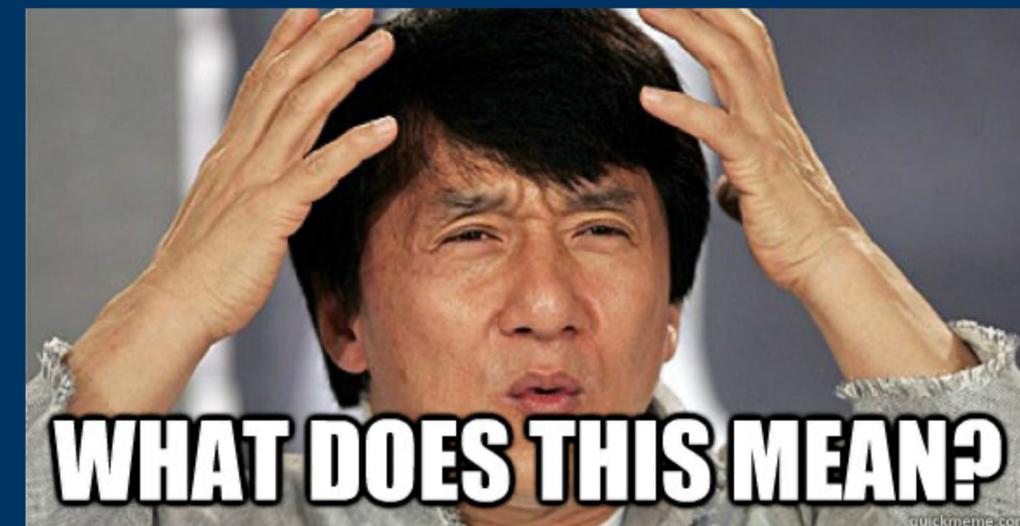

Back to Bohr

Indeed the **finite interaction** between object and **measuring agencies** conditioned by the very existence of the **quantum of action** entails—because of **the impossibility of controlling the reaction of the object on the measuring instruments** if these are to serve their purpose—the necessity of **a final renunciation of the classical ideal of causality** and a **radical revision** of our **attitude towards the problem of physical reality**.

N Bohr, Can a quantum-mechanical description of physical reality be considered complete? Phys. Rev., 1935, 48

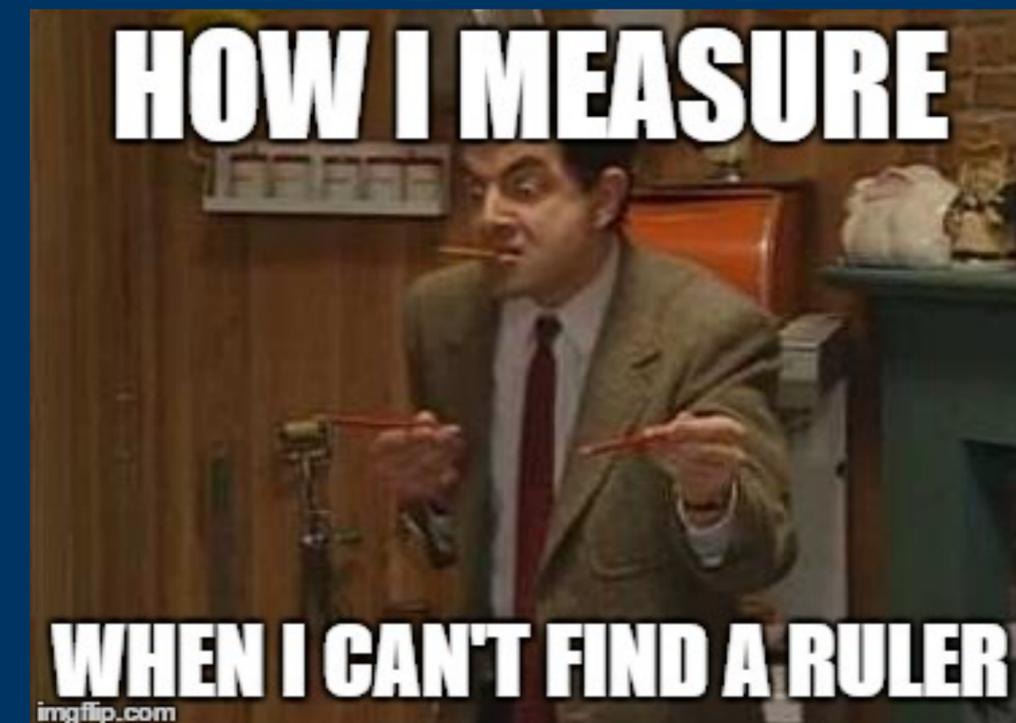

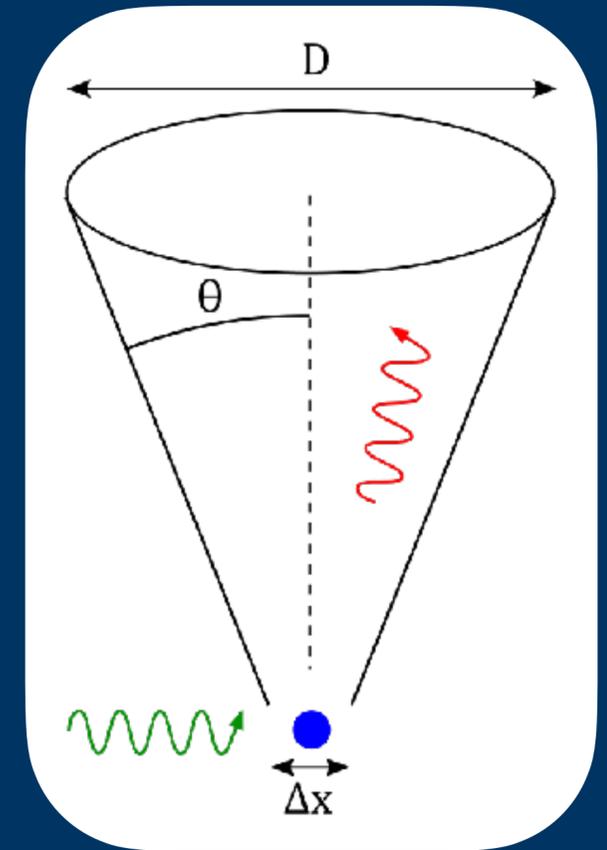

Now, the **quantum postulate** implies that **any observation of atomic phenomena** will involve an **interaction with the agency of observation not to be neglected**. Accordingly, **an independent reality in the ordinary physical sense can neither be ascribed to the phenomena nor to the agencies of observation**.

N. Bohr, Atomic Theory and the Description of Nature, Cambridge University Press, Cambridge, MA, 1934.

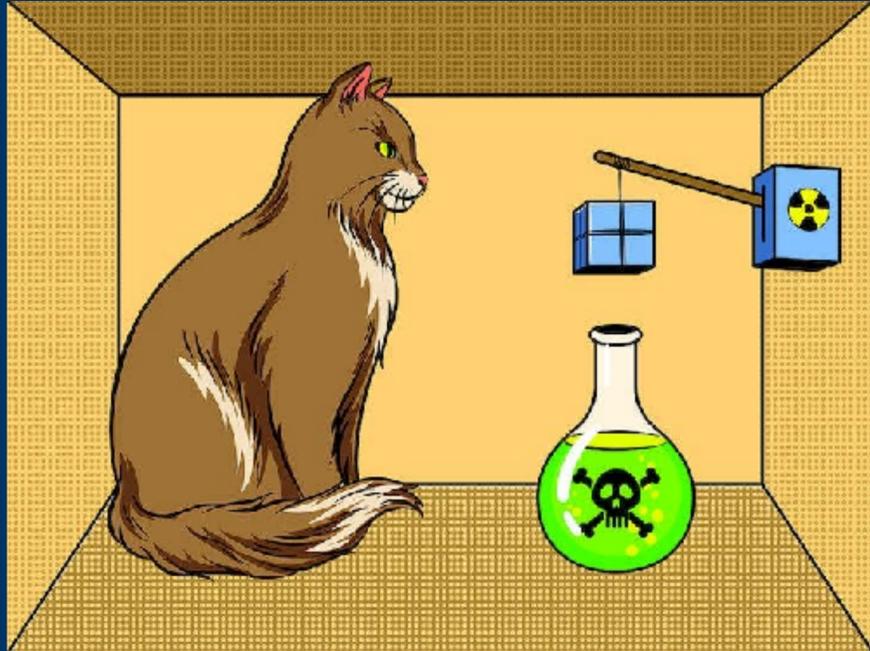

Bohr

- Every **measurement**
 - Involves an **interaction** between
 - Thing being **measured**
 - That doing the **measurement**
 - This interaction **cannot** be **measured** or **controlled**
 - Or we **change the experiment**
 - Any attempt to **measure** the **interaction**
 - **Introduces** a **new** measuring **device**
 - Which will **interact** in an **uncontrollable** way

Ok, lets talk about the cat...

Quantum state of the atom

Like the paths in the interferometer

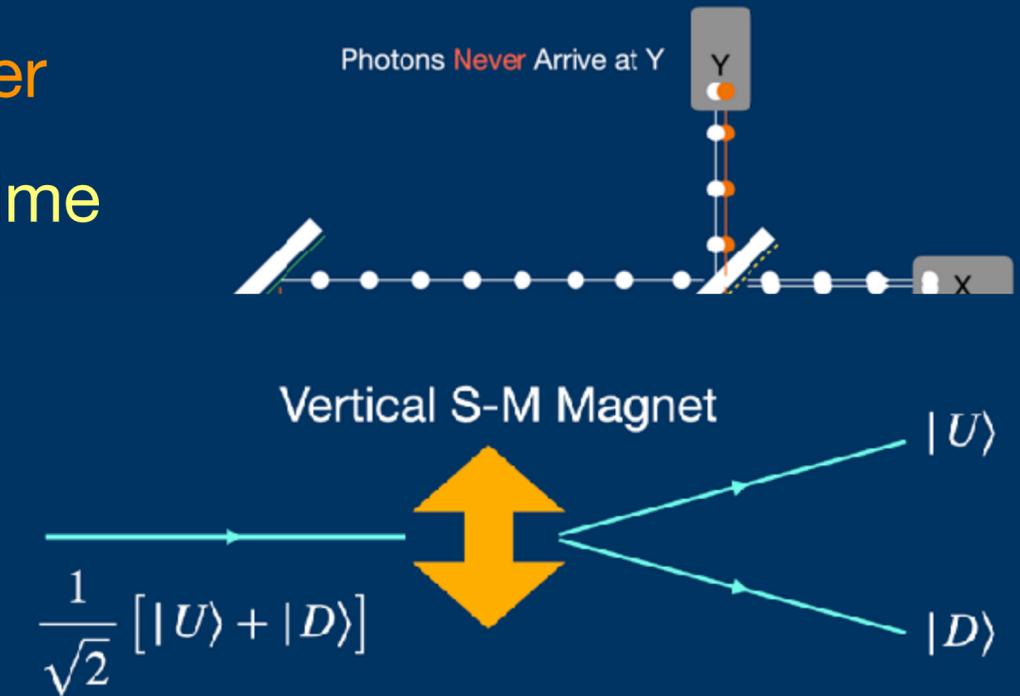

Until we measure, both at same time

Called a superposition

Atomic state a superposition of

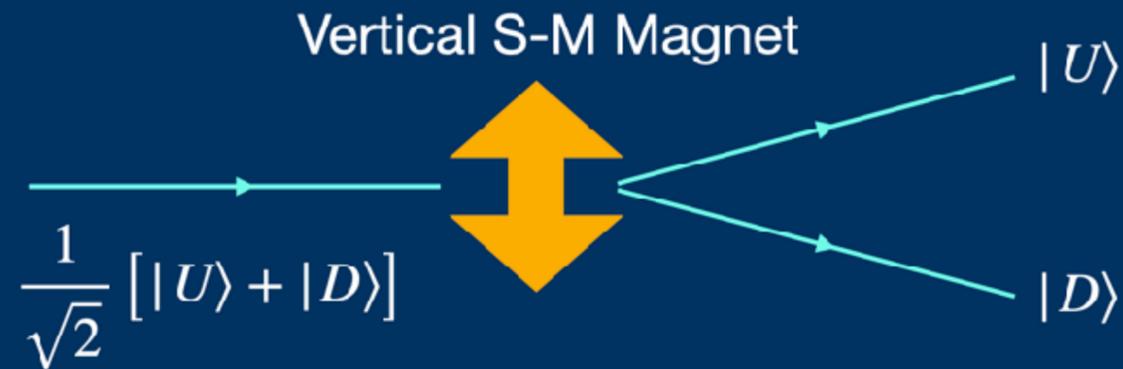

Decayed / Not decayed

Like the electron spin state...

Small aside

A superposition

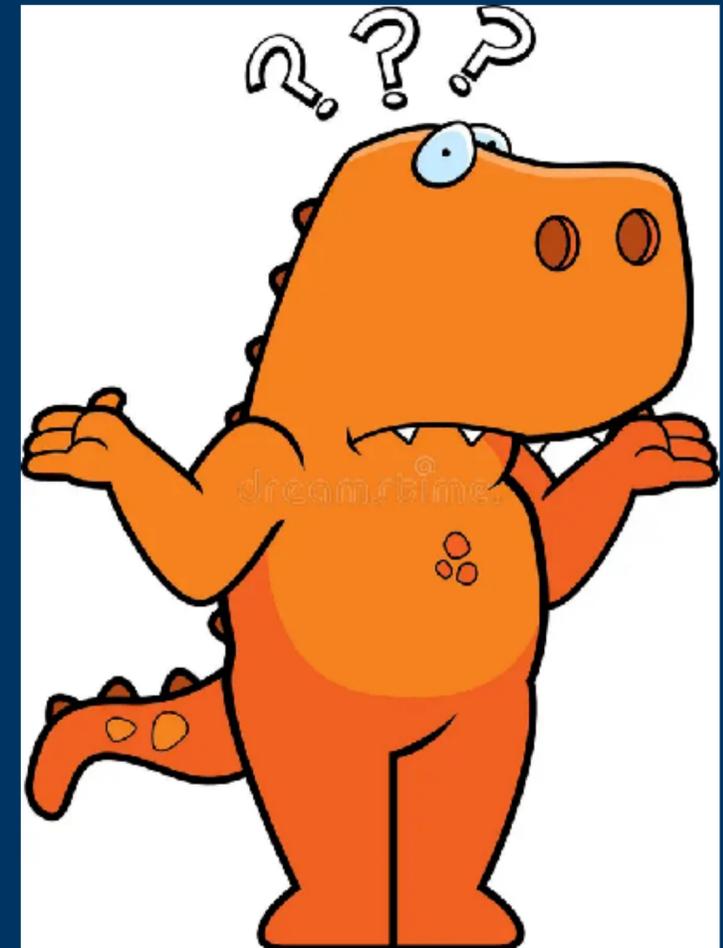

When the **smoky dragon** appears to be

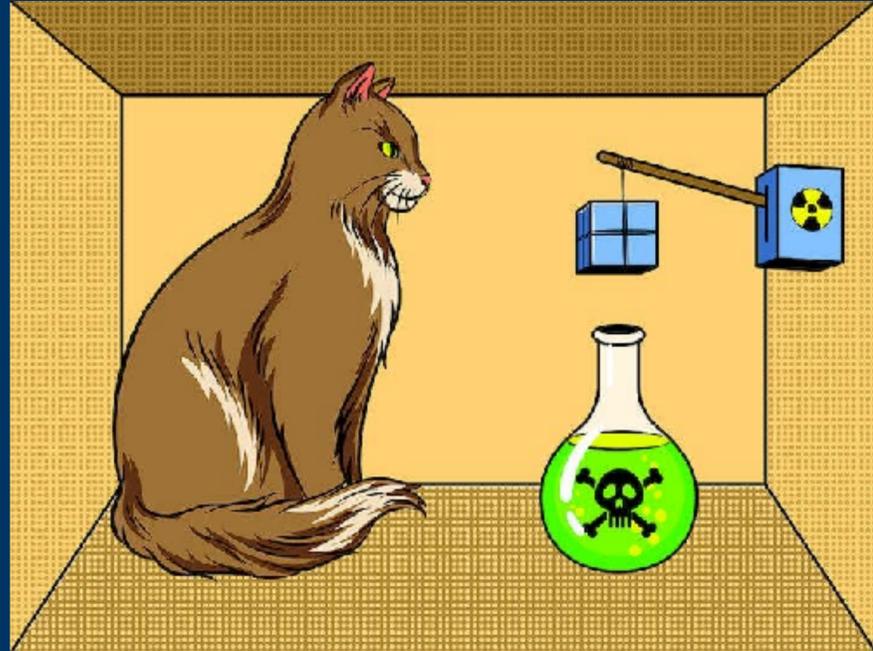

In **Several classical** states at the **same time**

Not possible in **classical physics...**

Measurement **collapses** it into **one** of the **states**

Ok, lets talk about the cat...

Quantum state of the **poison**

Like the **paths** in the **interferometer**

Like the electron **spin state**...

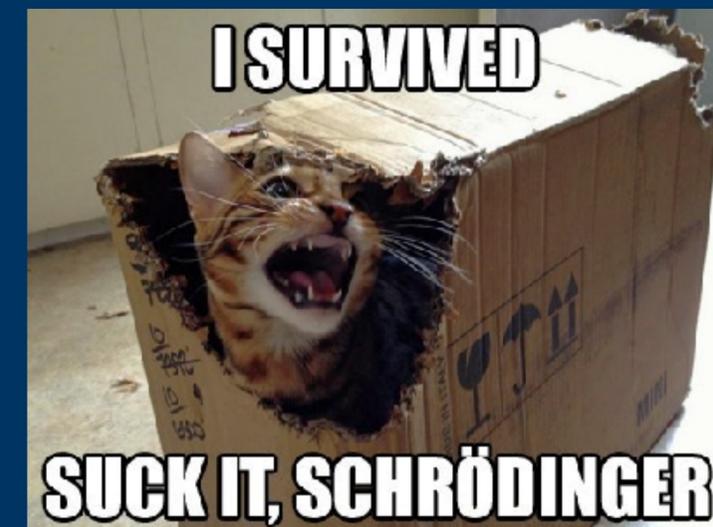

In **superposition**

As its state depends on the atom...

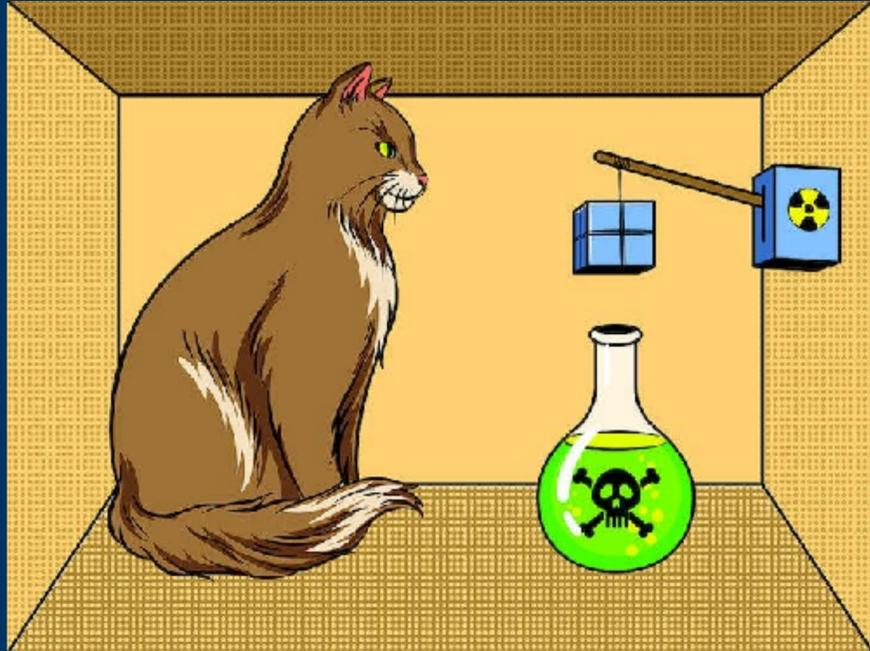

Entangled by the 'action' of **measurement**

$$\Psi = |\text{poison released}\rangle |\text{atom decayed}\rangle + |\text{poison not released}\rangle |\text{atom not decayed}\rangle$$

$$\Psi = |\text{red flask}\rangle |\text{red atom}\rangle + |\text{green flask}\rangle |\text{green atom}\rangle$$

Ok, lets talk about the cat...

When it **comes** to the **cat**

Why would it not be described by QM?

Then its **state** is **entangled** as well...

In **superposition**

Alive

Dead

Entangled into the overall state

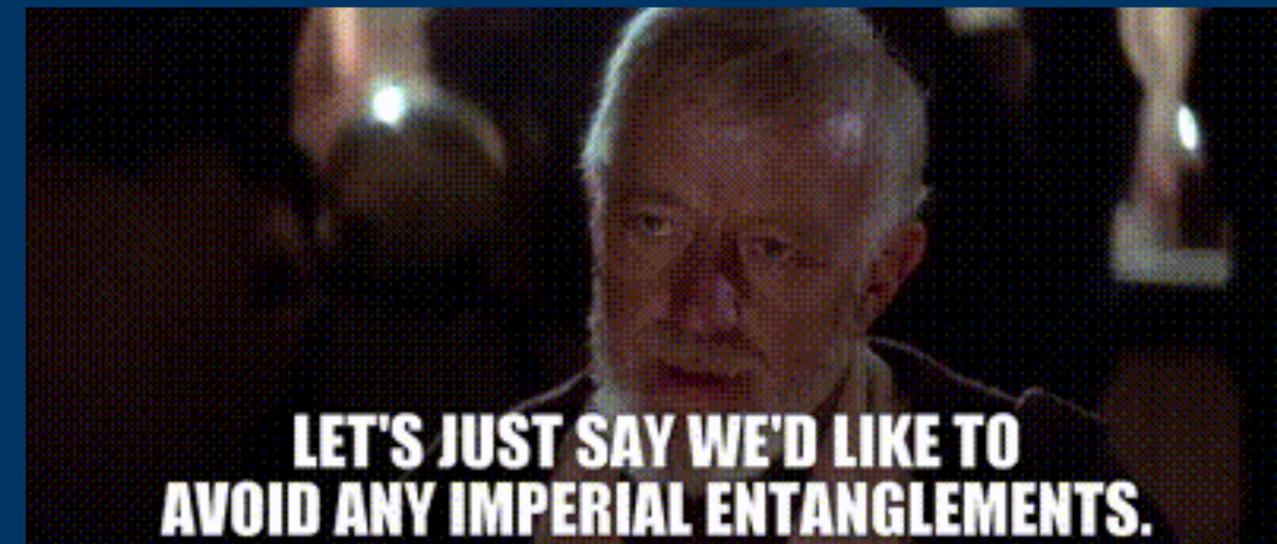

$$\Psi = |\text{Dead Cat}\rangle |\text{Poison}\rangle |\text{Radioactive}\rangle + |\text{Alive Cat}\rangle |\text{No Poison}\rangle |\text{No Radioactive}\rangle$$

Schrödinger devised this fable

To demonstrate how weird QM is...

Needs someone to look inside the box...

$$\Psi_{\text{bio}} = \left| \begin{array}{c} \text{Grumpy Cat} \\ \text{Red Biohazard} \\ \text{Red Atom} \end{array} \right\rangle + \left| \begin{array}{c} \text{Smiling Cat} \\ \text{Green Biohazard} \\ \text{Green Atom} \end{array} \right\rangle$$

Needs **someone** to **look** inside the **box**...

Or how do we know???

But then **according** to **QM**...

Our **observational state** is **entangled** in as well...

When does it **stop**?????

$$\Psi_{\text{bio}} = \left| \begin{array}{c} \text{Grumpy Cat} \\ \text{Red Beaker} \\ \text{Red Atom} \end{array} \right\rangle + \left| \begin{array}{c} \text{Smiling Cat} \\ \text{Green Beaker} \\ \text{Green Atom} \end{array} \right\rangle$$

Needs **someone** to **look** inside the **box**...

Or how do we know???

But then **according** to **QM**...

Our **observational state** is **entangled** in as well...

When does it **stop**?????

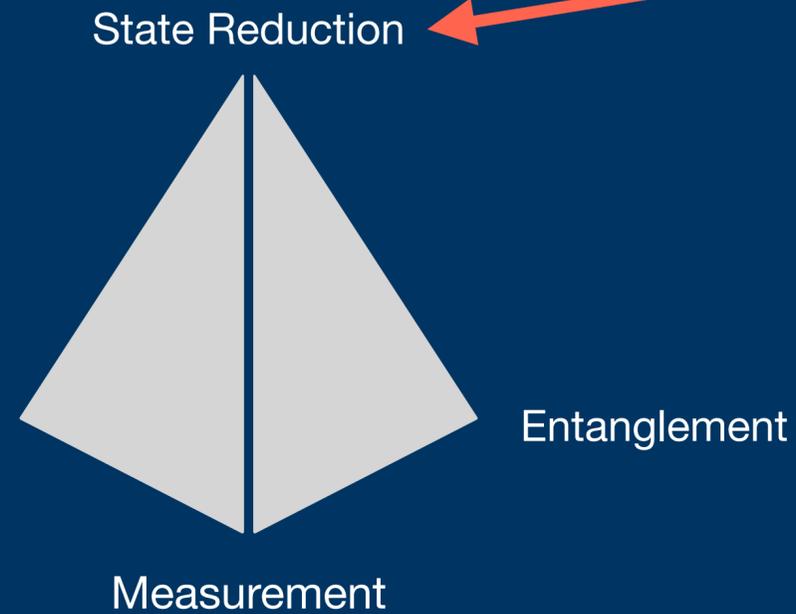

$$\Psi_{\text{bio}} = \left| \begin{array}{c} \text{Grumpy Cat} \\ \text{Red flask} \\ \text{Red atom} \end{array} \right\rangle + \left| \begin{array}{c} \text{Smiling Cat} \\ \text{Green flask} \\ \text{Green atom} \end{array} \right\rangle$$

The measurement problem

Chris Isham

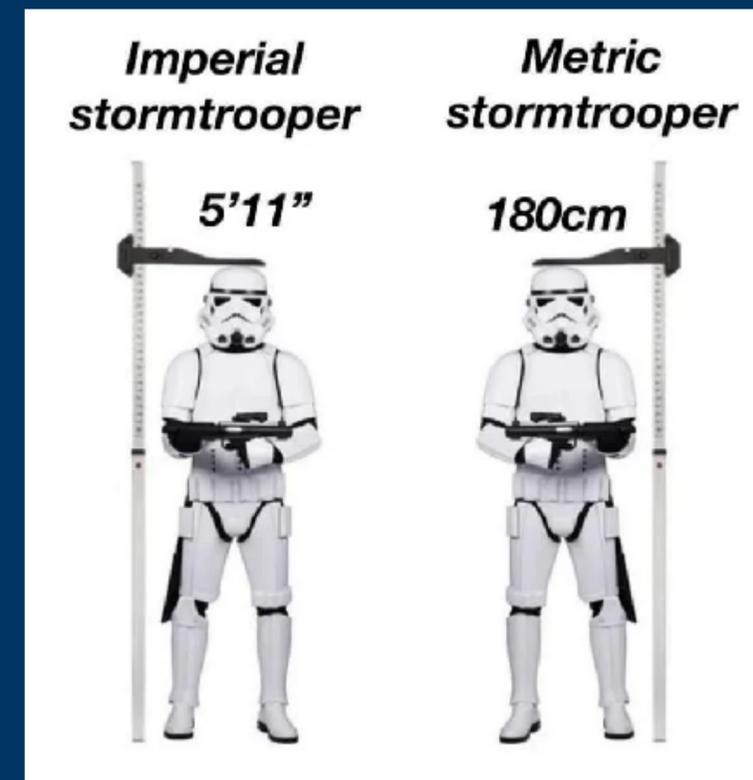

What breaks the superposition?
What actualises one of the options?

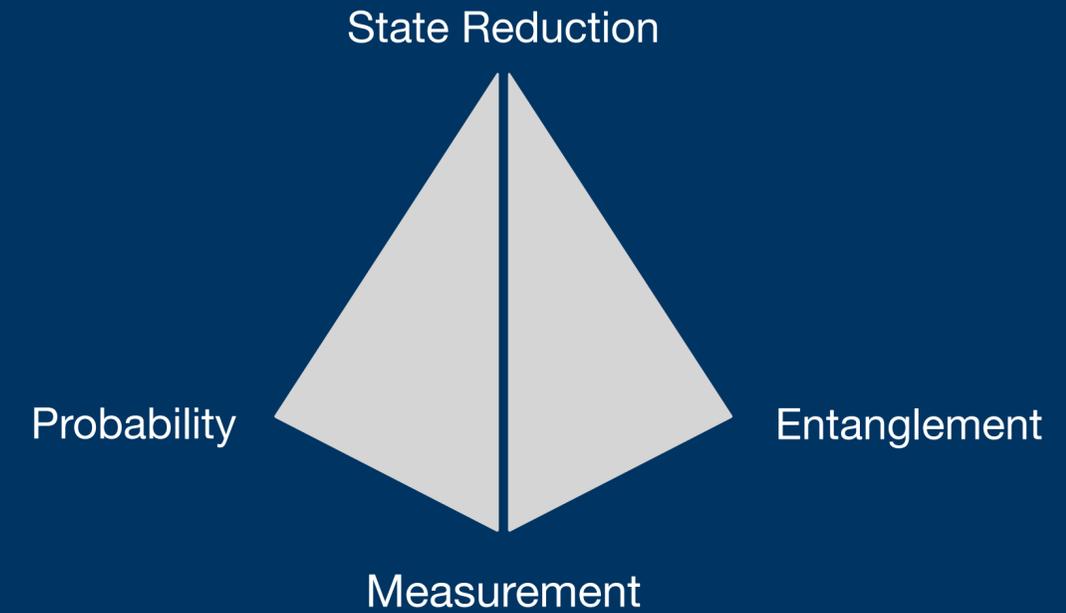

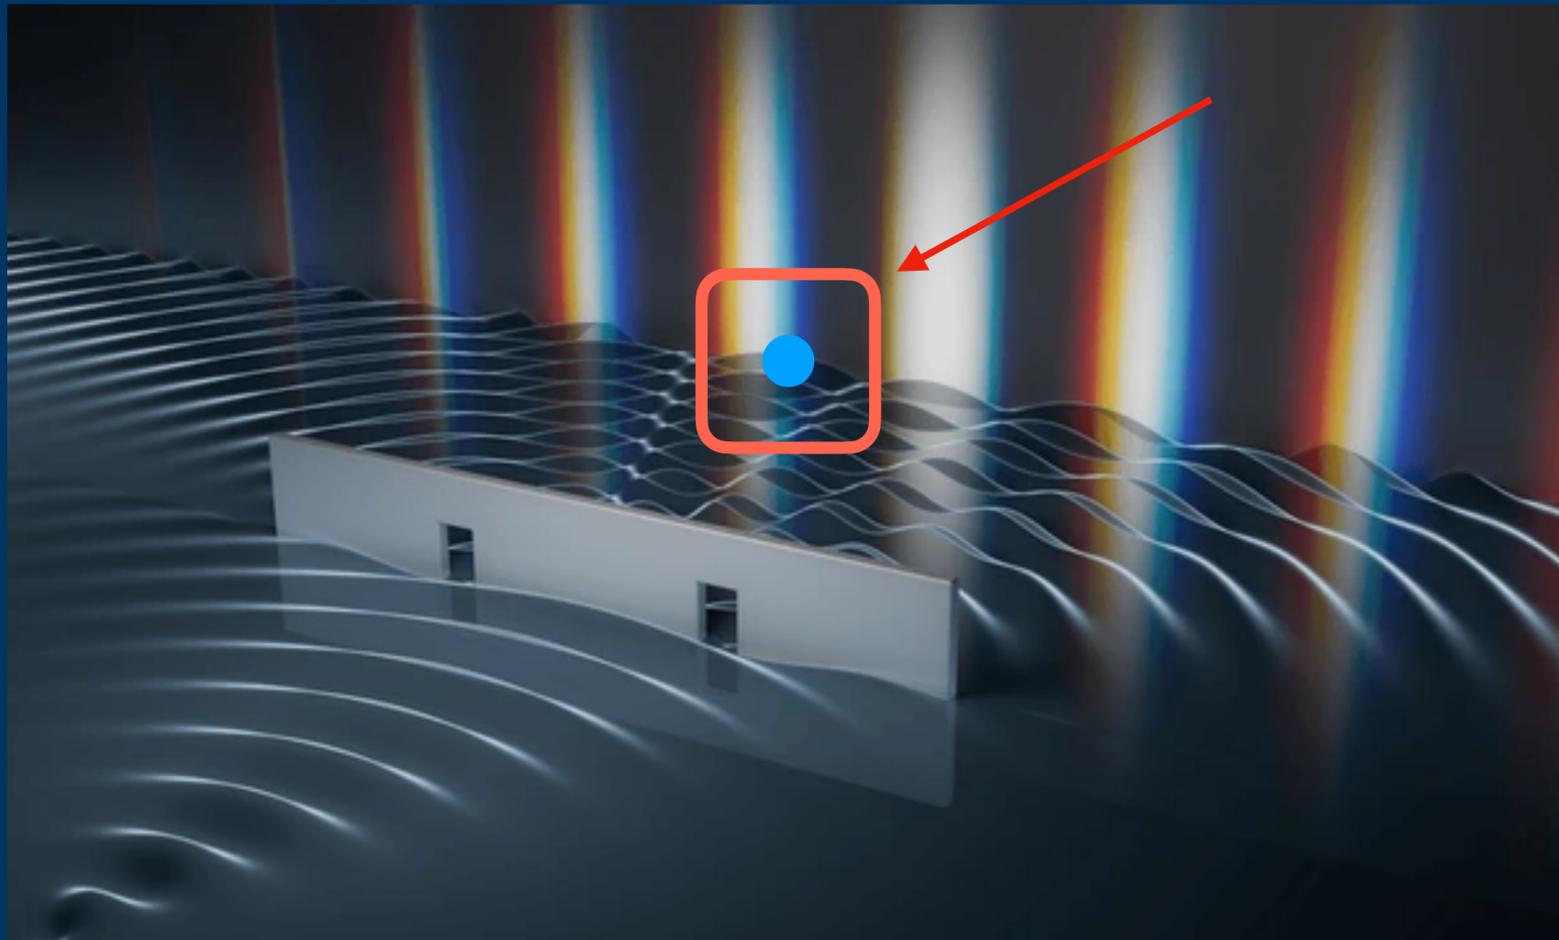

How do you stop entanglement spreading

What is a quantum probability?

What happens in a measurement?
Why is (is it?) measurement different?

The measurement problem

State reduction

When the **superposition collapses**

One of the **possibilities actualises**

All of the **others vanish...**

Not in the equations of QM...

Extra bolt-on **assumption**

$$i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} + V\psi$$

Bohm argued that the potentialities were latent in the particle and that they could only be brought out more fully through interaction with a classical measuring apparatus.

This of course is essentially the conventional view, so why did Bohm bother to make alternative proposals?

It was the complete absence of any account of the actual that troubled him.

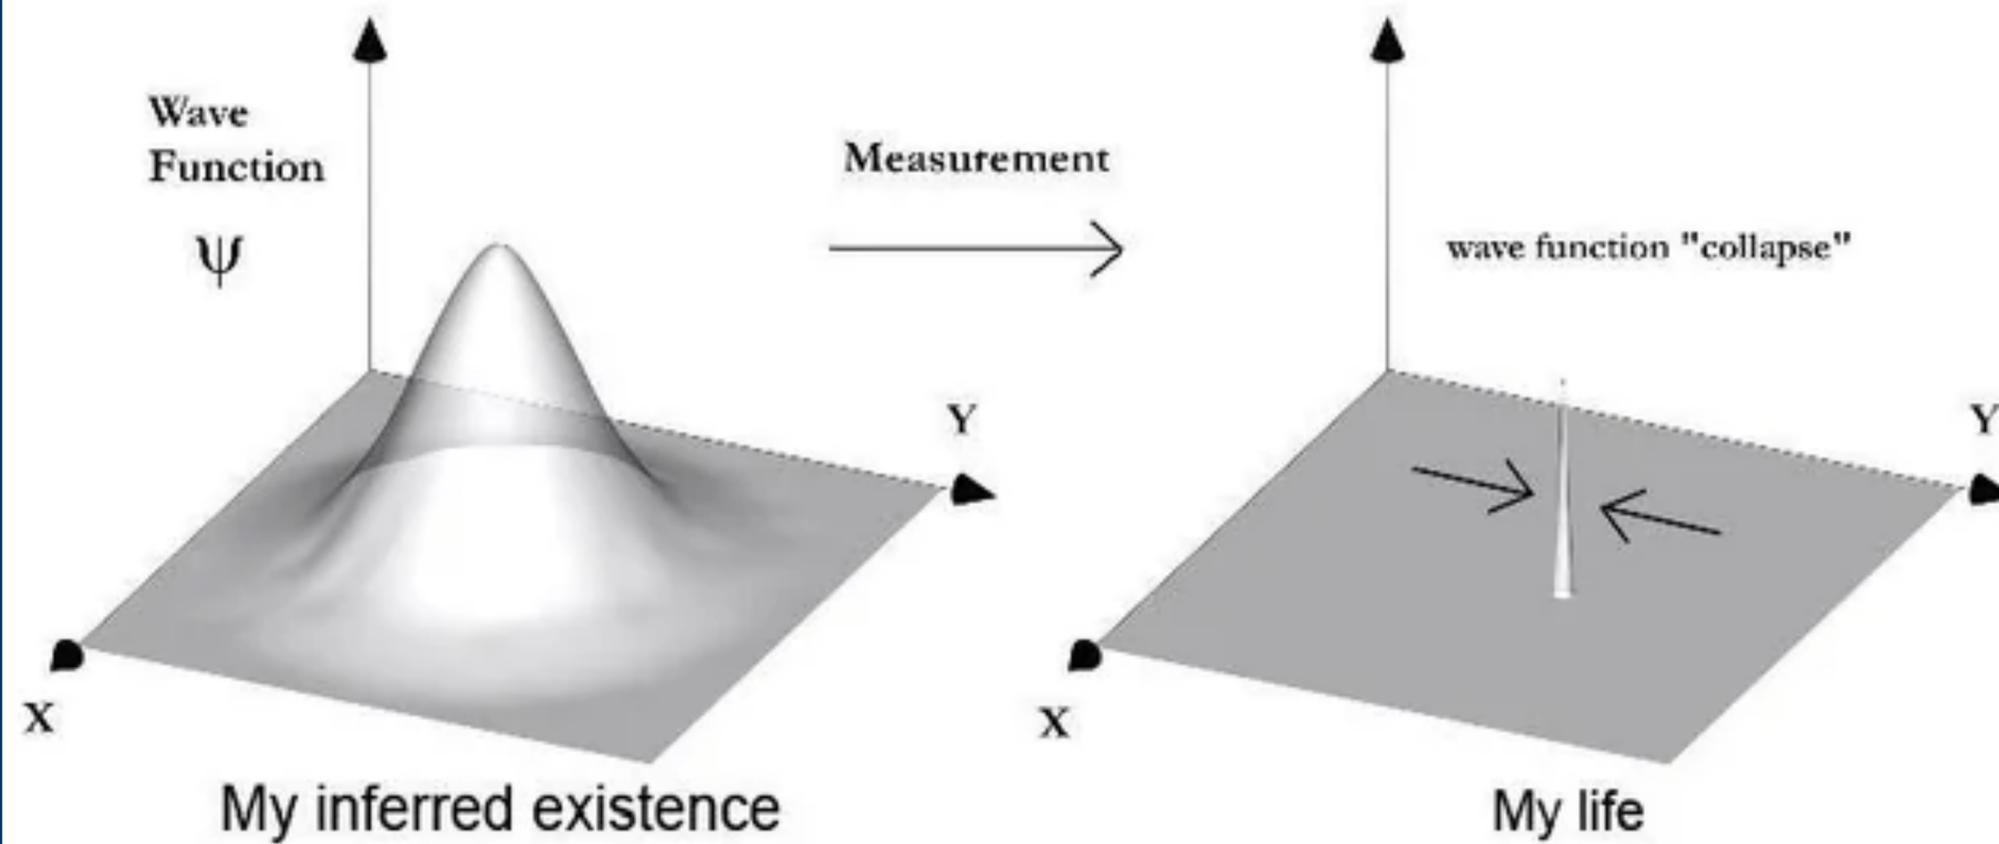

In the quantum formalism nothing seemed to happen unless and until there was an interaction with a measuring apparatus. There was no actualisation until some form of instrument was triggered.

Surely something triggered the instrument?

Why was the measuring instrument so different? Isn't it just another collection of physical processes governed by the same laws of physics?

The Copenhagen Interpretation:

When my wave function collapses into my pitiful existence...
